"Whereas the question of the level of the water in the Great Lakes and their connecting waters is of vital importance to the transportation facilities afforded by the harbor of Toledo, for the reason that any slight fluctuation of the water at the western end of Lake Erie and the lower end of Detroit river immediately affects the level of the water in the Maumee river which constitutes Toledo's harbor; and

Whereas the record of the water levels on the different lakes and channels shows that a slight fluctuation of the levels in Lake Michigan or Lake Superior results in a corresponding fluctuation of the levels of the lower lakes and connecting waters; and

Whereas our information is that the demand of the City of Chicago would tend to lower the level of Lake Michigan from six to eight inches, depending upon the amount of water abstracted by the growing demands of the city;

Be it resolved therefore, that this board does hereby seriously protest against the favorable consideration by the War Department on the request of the City of Chicago.

* * * * *

(Signed) J. D. Biggers,
Secretary."

Protest of the Cleveland Chamber of Commerce.

"Whereas the City of Cleveland is deeply interested in the development of navigation and commerce upon the Great Lakes; and

Whereas it has expended large sums in developing the harbor facilities of Cleveland and has asked and secured large governmental appropriations for harbor developments at Cleveland; and

Whereas any lowering of the lake level is likely to create necessity for additional expenditures to maintain the proper depth of water in harbors; and

Whereas it appears extremely probable that the subtraction of water from Lake Michigan through the Chicago Drainage Canal has been the cause, or a contributing cause the prevailing low depth of water during the season of navigation in 1911, and that any additional subtraction of water from Lake

Michigan would result in further lowering the level of the lower lakes:

Therefore be it resolved that the Cleveland Chamber of Commerce, representing the shipping and commercial interests of Cleveland, hereby protests against permission being granted to the Sanitary District of Chicago by the Secretary of War to increase the flow of water through the Chicago Drainage Canal beyond the amount of 4167 cubic feet per second, the quantity heretofore authorized.

Protest of Board of Control of Sandusky, Ohio, to Hon. Carl C. Anderson, February 24, 1912.

"The City of Sandusky through its Board of Control protest most emphatically against granting the application of the Sanitary District of Chicago for permission to divert 10,000 feet of water per second from the waters of Lake Michigan. The hearing will be given on the 28th at Washington, D. C.

May me ask you to see that this protest is properly registered."

(Signed by Clerk of Board of Control.)

Protest of Sandusky Business Men's Association, February 24, 1912.

"The Business Men's Association respectfully ask that you register our emphatic protest against the proposal to divert 10,000 feet of water per second from the waters of Lake Michigan upon the application of the Sanitary District of Chicago.

* * * * *

(Signed by the Secretary.)

Protest of the Buffalo Chamber of Commerce to the Secretary of War, April 1, 1912.

* * * * *

"The Buffalo Chamber of Commerce, representing the commercial interests of the City of Buffalo, realizing the injury to its commerce that the granting of the application would inflict in addition to the recognition of the right of a community to use the public waters for the purposes containing the commercial element to the detriment of other communities located on the lakes, seriously interfering with the use of the Great

Lakes as an avenue to transportation, does most earnestly register its protest against the granting of the application.

Government records show that up to June 30, 1911, federal authorities had spent at Buffalo and Black Rock in waterway improvements and in the maintenance of same, $7,932,380.68, and during the same period the citizens of Buffalo expended in the improvement of its harbor, $4,880,149.02, or a total of $12,812,529.70, which in itself is evidence of the importance of the Great Lakes to the commerce of Buffalo, and the necessity of avoiding any interference with the use of them as a factor in the developing of Buffalo commercially. The level of Lake Erie was one foot five inches lower in 1911 than in 1908, attributed not only to natural causes, but to the diversion of water from Lake Michigan under the present permit. This condition in the past few years has resulted in the lowering of the loading capacity of vessels, which has been reflected in the rates charged, causing loss not only to the shipping interests but to commercial interests as well, and as the tendency is to build larger and larger boats in order to reduce the transportation cost to a minimum, any action that will interefere with the operation of the large boats should be viewed as a public calamity.

The City of Buffalo stands ready to do its share toward providing harbor facilities that will permit its use by the largest vessels, but deem it an injustice that they be asked to increase this expense with no resultant compensation. We deeply feel that the granting of this application will work irreparable damage to the commerce of the City of Buffalo as well as other communities adjacent to Buffalo who use Lake Erie as a means to promote said commerce, and as other methods than that of dilution of sewage are now in vogue, and if all cities located on the Great Lakes should adopt the dilution method, it would nullify the use of the lakes for other purposes to the detriment of the people at large. Therefore, inasmuch as there are alternative methods that can be used for sanitation purposes, and the granting of the application would work a hardship on the citizens of Buffalo, we ask that a careful recognition of our views be given when the application should be finally considered.

Very respectfully submitted,

HARBOR AND RIVER COMMITTEE,
BUFFALO CHAMBER OF COMMERCE."

Resolution of Protest Adopted by Buffalo Lodge No. 1, Shipmasters' Association.

"Whereas the navigation of the Chicago river is at present extremely hazardous, dangerous and expensive for boats using the waterway, and

Whereas that undesirable state of affairs for boats is caused primarily through the necessity of supplying the Chicago Drainage Canal with the water it uses, and

Whereas the Chicago river "S" Branch is used to deliver the supply, thus creating a swift current which is constantly running, and

Whereas this supply is being drawn from Lake Michigan, thus increasing the flow from the lakes over its natural drainage which tends to lower lake levels, and

Whereas it is proposed to still further increase the drainage from the lake by building a canal to the Mississippi, or some point adjacent, and to supply the water necessary for said canal from the lakes through Chicago river and thus increase the hazard of navigation of Chicago river, and also lower lake levels, be it

Resolved that Buffalo Lodge No. 1, Shipmasters' Association, emphatically protest and oppose the said project of drawing more water from the lakes, or increasing the already dangerous current of Chicago river, and that this action be communicated to all sister lodges of this association and request their approval of the same, and that sister lodges send copy of this resolution to senators and congressmen of their respective districts and state.

W. E. Clark,
Chairman Harbor Committee."

Resolution of Ogdensburg Lodge No. 10, Shipmasters' Association.

"Whereas the navigation of the Chicago river is at present extremely hazardous and dangerous for boats using that water, and

Whereas that undesirable state of affairs for boats is caused primarily through the necessity of supplying the Chicago Drainage Canal with the water it uses, and

Whereas the Chicago river, south branch, is used to deliver the supply, thus creating a swift current which is constanly running, and

Whereas this supply is being drawn from Lake Michigan thus increasing the flow from the lakes over its natural drainage and tends to lower lake levels, and

Whereas it is proposed to still further increase the drainage from the lakes by building a canal to the Mississipppi or some point adjacent and to supply the water necessary for said canal from the lakes through the Chicago river and thus increase the dangers of navigation of the Chicago river and also lower lake levels, therefore be it

Resolved that Ogdensburg Lodge No. 10, Shipmasters' Association emphatically protest and oppose the said project of drawing more water from the lake or of increasing the already dangerous current of the Chicago river.

Respectfully submitted,

M. A. LEONARD,
Secretary."

Protest of Lockport Board of Trade to Secretary of War, February 26, 1912.

Board of Directors of Lockport Board of Trade in special meeting assembled, this afternoon have directed me to advise you of our opposition to the proposed diversion of two thousand cubic feet of water per second for sanitary purposes at Chicago.

Such diversion could not fail to affect lake commerce as it would lower the level and furthermore the utilization of water forces for sanitation purposes is certainly the wrong practice, especially as such water forces are the source of municipal water supply.

We therefore wish to be recorded in opposition to the proposed diversion and beg to remain,

Yours very truly,

WILLIAM A. DICKENSON,
Secretary.

Protest of Mayor of North Tonowanda, New York, to the Secretary of War, February 24, 1912.

"* * * Our people are opposed to this application for the reason that it would have a tendency, however slight, to lower the waters of the Great Lakes to the great damage of navigation thereon and the government has expended millions

of dollars to improve navigation on the Great Lakes in order to take care of the greatest commerce on earth and anything which could in the slightest degree affect the level of the lakes will be an injury to our people and to the large majority of the people of the United States. * * *"

Telegram from Mayor of Tonowanda, New York, to the Secretary of War, February 27, 1912.

"* * * * We wish to advise you that our city and this section is opposed to any further diversion of lake waters for so-called sanitary purposes and we think Chicago has already done more than her share of damage to our lake channels on which the government has spent so much money. * * *"

Telegram from Fred E. Signer of Association of Lake Lines, February 19, 1912.

"* * * On behalf of the Association of Lake Lines using the Chicago river in package trade earnest protest is made against granting such application. The present current makes navigation difficult and any increase would seriously impair movement of vessels if not make impossible handling of goods to and from industries located on river. * * *"

Protest from Canadian Niagara Power Co. to Chief of Engineers, February 26, 1912.

"* * * The undersigned corporation, Canadian-Niagara Power Co., as the owner of certain water power rights on the Niagara river in the province of Ontario through grants from the Canadian government, claims and is enjoying the right to use the waters of that river at Niagara Falls for power purposes. This company respectfully objects to and protests against any diversion of the water of Niagara river or of the lake attributary thereto which shall impair or imperil the dominant rights of this company, the lower riparian owner, and it objects to and protests against any diversion of such upper water for power purposes."

Protest of Niagara Falls Power Company to Chief of Engineers, February 26, 1912.

"* * * This company respectfully objects to and protests against any diversion of the waters of the Niagara river or of the lakes attributary thereto which shall impair or imperil the dominant rights of this company, the lower riparian owner, and it objects to and protests against any diversion of such upper waters for power purposes.

Protest of Shenango Furnace Company, Pittsburg, Pennsylvania, to Secretary of War, February 26, 1912.

"* * * We hereby protest against any action on the part of the government which will further tend to reduce the level of any of the lakes.

During the year 1911 the critical points in the lake routes were six inches lower than the average level for the last fifty-one years.

There is invested in lake shipping some two hundred million dollars. Our company alone have invested in five ships amounting to over two million dollars. Carrying capacity of these vessels during the year 1911 was reduced over ten per cent., due to the lowering of lake levels by natural causes which must have been aggravated by the new outlet at Chicago."

Protest of City Council of Winchester, Illinois, to Secretary of War, March 18, 1912.

"* * * Whereas the Sanitary District of Chicago has petitioned the Secretary of War to increase the flow of water from Lake Michigan down the path of the Illinois river, and believing such action would cause an overflow of the Illinois river, doing immense damage to land tributary to this city, causing a great financial loss to this city and county be it therefore

Resolved that we protest against such action by the War Department until the same can be done without damage to the land owners of the Illinois river valley. * * *"

SECRETARY'S OFFICE
BEARDSTOWN, ILLINOIS,

RESOLUTIONS PASSED BY THE ASSOCIATION OF DRAINAGE AND LEVEE DISTRICTS OF ILLINOIS

In Session at Springfield, Illinois, March 8th, 1912

Objecting to Increased Flow in Illinois River from [of] Water from Lake Michigan

1. WHEREAS, The turning into the valley of the Illinois river of waters from Lake Michigan by the Sanitary District of Chicago has caused great damage to the valley by overflowing valuable farming and timber lands and rendering them unproductive and unsanitary, and

2. WHEREAS, This great damage has been caused by the flow of less than 4,200 cubic feet per second, and

3. WHEREAS, The Sanitary District of Chicago is now asking the Secretary of War for a permit to increase the flow from Lake Michigan, down the path of the Illinois River, to 10,000 cubic feet per second, and

4. WHEREAS, Such flow will increase the damage done to the Illinois valley lands, and

5. WHEREAS, No provision has been made to prevent the damage that has been created by the flow from Lake Michigan, as exists now, to say nothing of the proposed increase, by either the Sanitary District of Chicago or the State of Illinois or the Federal Government, by the preparing of the channel of the Illinois River through the alluvial valley to care for same without damage, and

6. WHEREAS, 400,000 acres of the lands of the valley and numerous cities and villages are affected and damaged by the present flow and will be proportionately more damaged by the increased flow, and

7. WHEREAS, Great increase in cost to reclaim these lands and maintain the reclamation of the lands already reclaimed entailing cost to the thousands of land owners that can only be reimbursed by long expensive litigation, and

8. WHEREAS, The proper regulation of rivers of the United States is vested in the FEDERAL AUTHORITIES OF THE UNITED STATES, and any artificial changes of the natural conditions can only be made by authority of the Federal authorities and we cannot believe that it is any part of the policy of the United States either by sin or omission to damage the great

riparian interests in the lower valley or to prevent or handicap the development by reclamation of lands or their maintenance. On the contrary we look to the Federal authorities to remedy the present situation and to prevent further destruction of property. And recognizing the great authority of the United States in this matter,

9. THEREFORE, We respectfully represent that any higher water level in the river, which would be occasioned by this increased flow, would not only greatly damage and in many cases ruin the land owner, who has at great expense put such lands in cultivation, but also would render practically worthless hundreds of thousands of dollars of registered bonds, issued against said lands to pay for the reclamation of the same, many of which bonds are held in small amounts by investors of moderate means; therefore, be it

10. RESOLVED, By the Association of Drainage and Levee Districts of Illinois, in extraordinary session assembled, this 8th day of March, 1912, at Springfield, Illinois: That we protest against the granting of the permit for a greater flow through the valley of the Illinois river, and pray that no farther increase be allowed until the dams are removed and the channel so improved that the increased flow may be accommodated without damage to the lands of the valley and navigation be maintained. Be it further

RESOLVED, That this Association co-operate with all other interests affected by the improvement of the channel of the Illinois; and that a copy of these resolutions be transmitted to the secretary of war, to the chief of engineers of the United States army, the Governor of the state of Illinois, and all other interests affected.

Protest from Citizens of Chillicothe, Illinois.

"To the Honorable Henry L. Stimson,
Secretary of War,
Washington, D. C.

We, the undersigned owners of land adjacent to the Illinois river and citizens of the Illinois Valley in and near the City of Chillicothe, in the County of Peoria and State of Illinois, do hereby earnestly protest against and object to the granting of the petition of the Sanitary District of Chicago, in which they ask to be allowed to increase the water discharged by means of the Sanitary District canal from 3,200 ft. per second to 10,000 ft. per second.

We would respectfully show that the amount of water now discharged by said Sanitary District canal into the Illinois river has raised that river so as to cause its water to remain over the bottom lands much longer each year than formerly. It has caused vast areas of timber to die and has seriously impaired, if not entirely destroyed, the usefulness of many farms and large areas of land.

We would further show that it has entailed large expense upon those who have attempted to protect their lands by levees, in that it has imposed upon districts already formed, the necessity of increasing the size and height of their levees and the additional cost of pumping the water from such district against the increased amount of water in the river.

We would further respectfully protest against the granting of the prayer of said petition for the reason that said Sanitary District has not complied with the provisions of the statute with reference to compensation for lands damaged by reason of such overflow and resist the payment of such damage in such manner as to make it more expensive for the small land owner to recover his rights than he can afford.

All of which is respectfully submitted.

WM. M. MEAD,
President Business Men's Asso. Chillicothe, Peoria Co., Illinois.
C. B. ZINSER,
Treasurer, Business Men's Asso.
D. KELLY,
Chairman Partridge Drainage Dist., Chillicothe, Ill.
B. F. ZINSER,
Pres. First National Bank, Chillicothe, Ill.
ELLIS KIBBS,
Com. of Crow Creek Drainage Dist.
TRUETT MATTHEWS & Co.,
Bankers."

Protest of H. and E. F. Hunter, Chillicothe, Illinois, to the Secretary of War, March 12, 1912.

"As large owners of Illinois river bottom lands, we wish to enter our protest against permitting the Chicago Sanitary District to increase the flow of water through the Sanitary Canal from Lake Michigan. These Illinois river lands which

are among the most fertile in the world have already been seriously injured by the increased flow of water, damages for which can only be had after long and expensive litigation with the Sanitary District. This litigation is so expensive that it puts it practically beyond the range of the ordinary small land owner to get redress. We can see no reason why the residents of this valley should be subjected to all this loss for the sake of disposing of sewage which could be well taken care of in a better and more scientific way."

Resolution of Protest, City of Beardstown, Illinois.

"The following resolutions were adopted by the City Council, of the City of Beardstown, Illinois, at a regular meeting of the Council held Tuesday, March 5th, 1912, with instructions for the City Clerk to mail a copy of the said resolutions signed by the Mayor and City Clerk under the seal of the City of Beardstown to the Executive officers of the United States, Committee of Congress, Members of the National Congress and Senate from the State of Illinois and the Sanitary District of Chicago, to the Lakes-to-the-Gulf Deep Waterway Association, the Governor of the State of Illinois, the Rivers and Lakes Commission, the Mayor of Chicago, the Trustees of the Sanitary District of Chicago and the State Canal Commission, and others who may be particularly interested.

Whereas, The Sanitary District of Chicago, is now importuning the Secretary of War, to issue a permit, permitting an increase from 4,166 cubic feet per second to 10,000 cubic feet per second in the flow of waters from Lake Michigan down the Illinois river, and

Whereas, The present flow has caused an enormous amount of hardship and damage to the City of Beardstown and its inhabitants and to surrounding lands to say nothing of what an increase flow will mean, now

Therefore, be it resolved by the City of Beardstown through the Mayor and City Council that they hereby protest against such permit being issued, until the Illinois river is so improved by dredging and removal of locks and dams as to fit it to take care of the present flow, and that now asked for.

H. C. KEIL,
Mayor."

(Seal)
Attest:
R. B. MASLIN,
City Clerk.

Resolution of Protest by Beardstown Chamber of Commerce.

"Whereas, The turning into the valley of the Illinois river of waters from Lake Michigan by the Sanitary District of Chicago has caused great damage to the valley by overflowing valuable farming and timber lands and rendering them unproductive and unsanitary, and

Whereas, This great damage has been caused by the flow of less than 4,000 cubic feet per second, and

Whereas, The Sanitary District of Chicago is now asking the Secretary of War for a permit to increase the flow from Lake Michigan, down the path of the Illinois river, to 10,000 cubic feet per second, and

Whereas, Such flow will increase the damage done to the Illinois valley lands, and

Whereas, No provision has been made to prevent the damage that has been created by the flow from Lake Michigan, as exists now, to say nothing of the proposed increase, by either the Sanitary District of Chicago or the State of Illinois or the Federal Government, by the preparing of the channel of the Illinois river through the alluvial valley to care for same without damage, and

Whereas, 400,000 acres of the lands of the valley are affected and damaged by the present flow and will be proportionately more damaged by the increased flow, and

Whereas, Great increase in cost to reclaim these lands and maintain the reclamation of the lands already reclaimed entailing cost to the thousands of land owners that can only be reimbursed by long and expensive litigation, and

Whereas, The proper regulation of rivers of the United States is vested in the federal authorities of the United States, and any artificial changes of the natural conditions can only be made by authority of the federal authorities and we cannot believe that it is any part of the policy of the United States either by sin or omission to damage the great riparian interests in the lower valley or to prevent or handicap the development by reclamation of lands or their maintenance. On the contrary, we look to the federal authorities to remedy the present situation and to prevent further destruction of property. And recognizing the great authority of the United States in this matter, Therefore be it

Resolved, That the Chamber of Commerce of the City of Beardstown, Cass County, Illinois, do hereby protest against the granting of any permit to increase the flow of waters of Lake Michigan down or through the valley of the Illinois

River until after such time as the lower reach of the Illinois river is properly prepared to receive the same without damage to the lands of the valley and the agricultural and commercial interests; and be it further

Resolved, That the President and Secretary of this Chamber of Commerce are hereby directed to send copies of these resolutions to the Executive officers of the United States, Committees of Congress, Members of the National Congress and Senate from the State of Illinois, and the Sanitary District of Chicago, to the Lakes-to-the-Gulf Deep Waterway Association, the Governer of the State of Illinois and others who may be particularly interested.

Dated at Beardstown, Illinois, March 5th, 1912.

H. G. RUSSELL,
President.

(Seal)
The Beardstown Chamber of Commerce
Illinois (Seal) Beardstown

H. LERKEWICH,
Secretary.

Letter of Protest of Charles Schaaf to Secretary of War, February 23, 1912.

"I notice in the paper that on Feb. 28th you will give a hearing to the Sanitary District of Chicago for permission to divert an additional 10,000 cubic feet of water into the drainage canal. I wish to complain and say that the Sanitary District company has overflowed my land so that I am unable to make more than a living and if they are permitted to turn in more water my place will be a total loss. Before this water was turned in I could raise four or five thousand bushels of corn every year, now I do well to average one thousand a year—ten years ago my place was worth fifteen thousand dollars and now I would be *only to glad to sell for five thousand.* They ought to buy this bottom land before they are allowed to turn in the water. You may say sue them. Why we have been trying to sue them for 10 years but what can us poor farmers do with a company that is worth 50 to 60 millions, (*nothing*!) So I ask you in the name of God to not let them turn in more water, thanking you for any favors, believe me to be. * * *

CHARLES SCHAAF."

Protest of City Council of Rushville, Illinois, Dated March 5, 1912.

"Whereas, The turning into the valley of the Illinois river of waters from Lake Michigan by the Sanitary District of Chicago has caused great damage to the valley by overflowing valuable farming and timber lands and rendering them unproductive and unsanitary, and

Whereas, This great damage has been caused by the flow of less than 4,000 cubic feet per second, and,

Whereas, The Sanitary District of Chicago is now asking the Secretary of War for a permit to increase the flow from Lake Michigan down the path of the Illinois river, to 10,000 cubic feet per second, and,

Whereas, Such flow will increase the damage done to the Illinois valley lands, and

Whereas, No provision has been made to prevent the damage that has been created by the flow from Lake Michigan as exists now, to say nothing of the proposed increase, by either the Sanitary District of Chicago or the State of Illinois or the Federal Government, by the preparing of the channel of the Illinois river through the alluvial valley to care for same without damage, and,

Whereas, 400,000 acres of the lands of the valley are affected and damaged by the present flow and will be proportionately more damaged by the increased flow, and,

Whereas, Great increase in cost to reclaim these lands and maintain the reclamation of the lands already reclaimed entailing cost to the thousands of land owners that can only be reimbursed by long and expensive litigation, and,

Whereas, The proper regulation of rivers of the United States is vested in the *federal authorities of the United States* and any artificial changes of the natural conditions can only be made by authority of the federal authorities and we cannot believe that it is any part of the policy of the United States either by sin or omission to damage the great riparian interests in the lower valley or to prevent or handicap the development by reclamation of lands or their maintenance. On the contrary we look to the federal authorities to remedy the present situation and to prevent further destruction of property. And recognising the great authority of the United States in this matter, Therefore,

Be it, Resolved, That the City Council of the City of Rushville in Schuyler County, Illinois, do hereby protest against the granting of any permit to increase the flow of waters of

Lake Michigan down or through the valley of the Illinois river until after such time as the lower reach of the Illinois river is properly prepared to receive the same without damage to the lands of the valley and the agricultural and commercial interests."

Letter of Smith-Hippen Co., Pekin, Illinois, to Chief of Engineers, February 27, 1912.

W. H. Bixby,
Chief of Engineers, U. S. Army,
Washington, D. C.

Dear Sir:—

Your message of the 21st and letter of the 22nd refering to the hearing before the Secretary of War on the 28th, received. Referred same to a meeting of land owners and commissioners of the various drainage districts in this vicinity such as we could gather together and at their request wired you if it would not be possible to secure a postponement of the hearing or reserve the decision until a statement of the conditions could be prepared with a protest against increasing the present flow from Lake Michigan. Not hearing from you we suppose it was impossible for you to get this concession.

We know that if the lands owners and drainage commissioners are given a chance to make a protest, that they can demonstrate that the increased flow of water in the Illinois river without a corresponding depth of channel to provide for it will inculcate great loss on all of the drainage districts now organized or in the process of organization.

As a firm we now have invested in elevators along the Illinois river about $75,000.00. These houses were located and built on the basis of high water before the turning in of the extra water from Lake Michigan. This past year we were compelled to change our system of unloading at our Pekin elevator at a cost of over $1,100.00 because the increased floods each year overflowed our conveyors and rendered impractical this means of unloading boats which had been operated for years without any trouble with floods.

We find now that when the river is at flood state that the water is up over our foundations at practically every elevator and any increase in the volume of the water put it into all of our bins with a chance of great possible loss to both the buildings and their contents.

A further increase of water would mean that every river

house that we own would either have to be rebuilt or entirely remodeled and all approaches raised so as to get above any possible action of the water.

As most of the grain reaching our river houses is hauled over bottom roads, these would also have to raised a corresponding amount or our business would be hampered and handicapped by the longer period in which the flood water would submerge the roads.

The great difficulty with the flow of water from the drainage canal is that it is regulated entirely to suit the needs of the Sanitary District without regard to the loss or inconvenience to the river valley.

We find that the time of our greatest floods is the time at which the greatest amount of water is passed over the bear trap. Quoting from the Chicago Evening Post of April 30, 1909—"Flow in the drainage canal nearly doubled to meet emergency of record-breaking rainfall." And again from the same issue—"In the sanitary canal the flow first was increased from a normal of 350,000 cubic feet of water a minute to 480,000 cubic feet, and when that augmented flow failed to keep the river current flowing away from Lake Michigan, instructions were phoned to Lockport to lower the dam still farther to permit 600,000 cubic feet to pass over it each minute."

There are no records accessible to us by which we can prove these figures but we do know that our floods are augmented each year very considerably by the excessive amount of water let in through the drainage canal and a further increase of this amount would work us very serious damage.

We would welcome the time when ten thousand second feet of water could be passed down this river if the channel were prepared to receive it, but with conditions as they are at present we think it would be of great loss to all of the valley interests to increase the flow.

Yours very truly,

SMITH-HIPPEN COMPANY,

by A. J. AYDELOTT."

Protest of Citizens and Property Owners of Greene County, Illinois, to the Secretary of War, March, 1912.

"We, the undersigned citizens residing in Greene County, Illinois (which borders on the Illinois river), do hereby most earnestly protest against the granting of permission to the Sanitary District of Chicago to turn into the Illinois river valley any greater amount of water than the present flow of 4,200 cubic feet per second, until such time as by reason of the removal of the dams and other obstructions now in said river, a sufficient channel will be prepared to accommodate such increased flow without the great damage to agricultural and other interests that would necessarily result from such increased flow with the river in its present condition.

In support of this protest we respectfully call your attention to the fact that this increased volume of water is not needed for the purposes of navigation: that there are in our county thousands, and in the valley of the Illinois tens of thousands, of acres, of rich farming lands now in cultivation and highly productive, which by reason of their low elevation will be practically ruined in case the water level in the river is materially increased, and especially is this true by reason of the fact that the dams across the river have already raised the level at low water to a point which approaches the natural level of those lands. We most respectfully insist that the increased water level in the river, which would be occasioned by this additional flow, would not only greatly damage, and in many cases financially ruin, the land owners, who have, by years of unremitting toil and privation and the expenditure of vast sums of money, converted these lands from their natural condition of swamps into fertile and productive fields, but would also render practically worthless millions of dollars of drainage bonds which have been issued against these lands to pay off the cost of building levees, excavating ditches and installing pumping plants, etc., many of which bonds are held in small amounts by investors of moderate means, some of whom have the savings of a lifetime invested in them.

We therefore most earnestly request you to withhold your official permission to the turning into this fertile valley of this great increase of water, which, under present conditions, would be bound to cause such great and irreparable loss and damage to so many of our citizens.

All of which is respectfully submitted."

United States of America,

United States of America,
Complainant,
vs.
The Sanitary District of Chicago,
Defendant.

Equity No. 114.
C. C. No. 29,019.

STIPULATION.

It is hereby stipulated that the matter on pages 3601 to 3845, inclusive, being extracts from public hearings, briefs, letters, telegrams, and resolutions in connection with the application of the Sanitary District of Chicago of February 5, 1912, to divert 10,000 cu. ft. of water per second from Lake Michigan, may be considered in evidence with like effect as if witnesses were called and originals were produced and identified in this case, subject to all objections as to materiality, relevancy and competency, but neither complainant nor defendant waives by this stipulation any objections as to competency, relevancy and materiality of any similar or like matters offered by the other party relative to said hearing.

CHAS. F. CLYNE,
United States Attorney.
EDMUND D. ADCOCK
Attorney for Sanitary District of Chicago.

Chicago, October 1st, 1914.

EXTRACTS FROM APPROVALS OF VARIOUS ASSOCIATIONS AND INDIVIDUALS, AND BRIEFS ON BEHALF OF THE STATE OF ILLINOIS AND THE CITY OF CHICAGO.

Letter of Approval by Major Thos. H. Rees, U. S. Engr., to Chief of Engrs. U. S. Army, Jan. 17, 1910.

"1. In connection with 1st indorsement of this date on letter from Chief Engineer, Sanitary District of Chicago of

January 10, 1910, I have the honor to submit the following report and recommendations:

2. The only questions in connection with this application that seem to require consideration by the War Department are the following:

(a) The reversal of the flow of water in the Calumet River.

(b) The change of hydraulic grade in the Calumet River.

(c) The velocity of current that may be generated in Calumet River.

(d) The diversion of water from Lake Michigan.

3. Although not stated in the application, I am informed by the Chief Engineer of the Sanitary District that it is proposed to provide for a flow in Sag Channel—of 2,000 cubic feet per second. The natural flow in the Calumet River varies between wide ranges and is largely affected by the stage of Lake Michigan. The drainage basin has an area of 825 square miles and the mean annual rainfall of this region is 33 inches. Assuming a run-off of 40 per cent. the average discharge of the river would be 800 cubic feet per second. During dry periods the discharge is practically nothing and a temporary rise in lake level sometimes causes a current up-stream. During freshets the discharge is greatly increased and may at times greatly exceed the 2,000 cubic feet per second proposed to be diverted into the Sag-Channel. At such times the surplus would discharge into Lake Michigan without any reversal of flow in the lower Calumet River. A large part of the sediment and sewage from the Grand Calumet and Little Calumet rivers would be carried into the Sag-Channel, thus diminishing the deposits of such material in the lower Calumet River and in Calumet Harbor. The reversal of flow in Calumet River would not be detrimental to navigation interests provided the reversed current has a moderate velocity.

4. A reversal of the flow in the Calumet River will necessarily cause a downward slope of the water surface from the Lake toward the Sag-Channel, thus lowering the hydraulic grade and slightly diminishing the depth of water in the channel. In the existing channel a flow of 2,000 cubic feet per second will cause a slope of about 1:1,000,000 and at "the Forks," which is the head of projected improvements, the hydraulic grade would be lowered only about 0.4 of an inch. This is negligible and the lowering of the hydraulic grade would not be prejudicial to navigation.

5. A flow of 2,000 cubic feet per second would generate in the existing channel a mean velocity not exceeding 0.45 feet

per second (0.3 miles per hour). Through bridge openings 120 feet wide the mean velocity would be about 0.83 feet per second (0.55 miles per hour). These velocities would not be detrimental to navigation interests.

6. It seems to have been condeded both by the War Department and by the International Waterways Commission that, subject to possible future action by the Courts or the Congress of the United States and to possible treaty stipulations with the Dominion of Canada, the Sanitary District of Chicago may divert from Lake Michigan through its Sanitary and Ship Canal, 10,000 cubic feet of water per second and no more, provided the currents thereby generated in navigable channels of the United States shall not be unduly harmful to navigation interests by reason of excessive velocities. The several outlets through which the Sanitary District proposes to effect this diversion are: The North Shore Channel from Lake Michigan at Wilmette, Ill., to the North Branch of Chicago River at Lawrence avenue (authorized and under construction); the Chicago River together with the South Branch and West Fork to Robey street (authorized and nearly completed); the 39th Street Conduit and pumping station (in operation); the Calumet River by means of the proposed Sag-Channel from the Little Calumet River at Blue Island to the main drainage canal at Sag. If the total diversion through all of these outlets be limited to 10,000 cubic feet per second and if the currents be restricted to harmless velocities, I can see no reason, so far as the interests of navigation are concerned, for denying this application of the Sanitary District of Chicago.

7. It is therefore recommended that this application of the Sanitary District of Chicago be granted subject to the following conditions:

1. That the total diversion of water from Lake Michigan by the said Sanitary District through all of its channels and outlets shall not exceed the rate of 10,000 cubic feet of water per second.

2. That the current generated in any navigable channel of the United States used in part for such diversion of water from Lake Michigan shall not have a mean velocity exceeding one and one-quarter (1¼) miles per hour.

3. That detailed plans showing the proposed location and method for the connection of the Sag-Channel with the Calumet or Little Calumet River and showing also any changes or alterations proposed to be made in said rivers shall be sub-

mitted by the Sanitary District for prior approval by the War Department, and this part of the work shall be subject to supervision by the U. S. Engineer Officer whose address is Chicago, Ill.

4. That this permission shall not be construed as authorizing the invasion of any legal rights of corporations or individuals, municipal or private, or as exempting the grantee from responsibility for damages that may result from the works herein authorized.

THOS. H. REES,
Major, Corps of Engineers."

Letter of Approval by Major Thos. H. Rees, U. S. Engr., to Chief of Engr., U. S. Army, Feb. 21, 1910.

"1. Replying to your letter of February 16, 1910 (E. D. 28918/265), in regard to the application of the Sanitary District of Chicago for permission to divert water from Lake Michigan through a proposed Calumet-Sag Channel, I have the honor to refer to the report of Colonel W. H. Bixby, Corps of Engineers, of December 4, 1906, from which I quote, 'so far as it provides for keeping a part of the Calumet Basin sewage from flowing into Lake Michigan and for diverting the same into the Sanitary District Canal and Illinois River the project deserves all reasonable and allowable commendation and encouragement. * * * The reasons given oblige me at present to recommend against any present favorable consideration of the present request unless the 10,000 cubic feet per second flowage possibly allowable through the Chicago River be reduced by the amount allowed to the Calumet. Otherwise I see no special objection to the permit as requested so far as concerns the interests of navigation.'

2. The recommendations of the Chief of Engineers of February 23, 1907, quoted by the Secretary of War in his memorandum of March 14, 1907, refer to the conclusions of the International Waterways Commission as set forth in report of January 4, 1907, printed as War Department Document No. 293. This report concludes with the following words:

'We therefore recommend that the Government of the United States prohibit the diversion of more than 10,000 cubic feet per second for the Chicago Drainage Canal.'

3. On May 4, 1906, the Secretary of War transmitted to the President for submission to Congress a report of May 3, 1906,

by the International Waterways Commission upon the preservation of Niagara Falls printed as Senate Document No. 434, 59th Congress, 1st Session in which 'The Comission therefore recommend that * * * a diversion for sanitary purposes not to exceed 10,000 cubic feet per second be authorized for the Chicago Drainage Canal. * * *'

4. I cannot find any definite concurrence by the Chief of Engineers or the Secretary of War in the conclusions and recommendations of the International Waterways Commission above quoted but the 'conclusions' were referred to by the Chief of Engineers to support his recommendations and the 'recommendations' were transmitted by the Secretary of War for submission to Congress without adverse comment. Therefore I stated in my letter of January 17, 1910, that it seems to have been conceded by the War Department that the Sanitary District may divert from Lake Michigan through its Sanitary and Ship Canal 10,000 cubic feet of water per second.

5. The former application of the Sanitary District which was denied in March, 1907, asked for approval of plans which contemplated an ultimate total diversion of 14,000 cubic feet of water per second from Lake Michigan. The application of January 10, 1910, contemplates a total diversion of 10,000 cubic feet per second.

THOS. H. REES,
Major, Corps of Engineers."

Letter of Approval by P. T. Cook to Secretary of War, Feb. 29, 1912.

"Subject, Increasing Second-Feet to Chicago Drainage Canal.—Sir: I am a student of the Great Lakes since 1875, when I began to hunt and fish on St. Claire Flats. My Indian and half-breed punters instilled the notion that there was a regular cycle of high and low water of about eleven years from crest to crest, with a difference of two to three feet. My personal experience was the purchase of a low lying farm on Huron Point, Lake St. Claire, and its sale several years later. When I bought, the farmer had been drowned out for a couple of years. When I sold, the entire farm could be plowed to the shore of the lake.

I think I have read of this cycle in the writings of Schoolcraft and Cass. I have heard it from the boatmen at Mackinac, and my guides on Superior. My own opinion is that the

cycle is irregular and dependent on the rainfall of the Great Lakes basin. A comparison of the rainfall from the records of the Weather Bureau with the gauge readings of the upper lakes should verify or disprove the tradition.

Twenty-five years ago, Capt. Lockwood, then in charge of rivers and harbors at this point, estimated the northward current on the east side of Lake Michigan at one-quarter to one-half mile per hour.

At the slowest rate, the 7,000 second feet now allowed the Drainage Canal would deduct 0.1416 feet from a width of twenty-five miles, and reduce the level of the lake 0.04423 feet or one-half inch.

Assuming locks 150 feet wide, 900 feet long with 22 feet over sill and assuming that lockages are made continuously at the average rate of those at Sault Ste. Marie for 1909, 35 Min., and allowing 30 per cent. displacement, 2,315 second-feet would supply the water, leaving 4,685 feet for power.

As the present supply gives a speed of two and one-half miles per hour in the rock-cutting sections of the canal, it is evident that the call for more water comes only from the neighborhood of the turning basins and from the waterwheels at Lockport.

If it should be found necessary to give some water for the basins, I respectfully suggest that the amount be limited to 2,500 feet, and the proviso be inserted in the grant that this extra amount shall, at all times, be available for ship canal use, and that no vested rights shall accrue by reason of its use for other purposes, no matter how long such use may become.

As to the effect on the climate of Michigan, the fears of my neighbors are groundless.

One illustration is enough. The Hon. William Livingstone is quoted, this morning, as saying: 'Lake Superior has fallen .8 foot in the last four years, Lakes Michigan and Huron .8 foot in two years, Lake Erie a .8 foot in two years and Lake Ontario 1.5 feet.'

The fact that Superior, Michigan and Huron show the same drop is conclusive proof that the canal is no factor in the lake level.

P. T. Cook."

Letter of Approval by Illinois Rivers and Lakes Commission, March 11, 1912.

"In connection with the request of the Sanitary District of Chicago for permission to extract a volume of ten thousand cubic feet of water per second from Lake Michigan, the Rivers and Lakes Commission of the State of Illinois begs to submit for your consideration the following statement of facts:

First: This volume of water is required in order to comply with the laws of Illinois.—Sanitary District Act of Illinois General Assembly, 1889.

Second: The connection between the Great Lakes and the Mississippi Valley was provided for by Congressional Act in 1832, as held by the Supreme Court of the United States in the case of Missouri *vs.* Sanitary District of Chicago.

Third: That the Sanitary and Ship Canal, as constructed, is of a size necessary under present conditions to carry out the waterway policy of the United States formed in 1832.

Fourth: The full project of the State of Illinois contemplates the sanitation of Chicago and of the Illinois River valley; the construction of a navigable waterway giving to this region facilities similar to those provided by the United States Government in the Ohio River and in the St. Mary's and other interlake channels, the same to be paid for so far as possible out of the water power created as incident to the work.

Fifth: We call your attention that this is a project distinctly in accordance with present-day views as to the use of public property for the general welfare and shows a marked advance over the methods heretofore used in creating public improvements.

Sixth: Opposition to this plan comes from and is urged in behalf of special interests, which derive almost exclusive benefits from the Government appropriations for the Great Lakes, whether spent in deepening channels, building locks or improving harbors.

Seventh: For entire confirmation of these facts, we refer you to the arguments of Mr. Isham Randolph, Mr. Gardner S. Williams and Mr. Robert R. McCormick.

ROBERT R. MCCORMICK,
Chairman."

Letter of Approval by Senator S. M. Cullom, March 20, 1910.

"I have just received the enclosed resolution adopted by Board of Trustees of the Sanitary District of Chicago, in reference to the increase in the flow of waters made necessary by the proposition to reverse the flow of the Calumet. It seems to me that there is merit in the proposition that a permit should be granted along the lines asked for by the Drainage Board.

I send the resolution to you, to again call your attention to the matter, in the hope that you may see your way clear to grant the permit requested.

Sincerely yours,

S. M. CULLOM."

Resolution of Approval by Chicago Association of Commerce.

"We respectfully invite your attention to the attached certified copy of a resolution adopted today by the Executive Committee of this Association with respect to the application of the Board of Trustees of the Sanitary District of Chicago to take additional water from Lake Michigan.

THE CHICAGO ASSOCIATION OF COMMERCE,
By E. U. KIMBARK,
President."

Resolution Adopted by the Executive Committee of the Chicago Association of Commerce in Regular Meeting Assembled on Friday, March 22, 1912.

"Whereas, the Board of Trustees of the Sanitary District of Chicago has petitioned the United States Government for an increased flow from Lake Michigan of from 4,167 cubic feet per second to 10,000 cubic feet per second, of which 2,000 cubic feet is to come through the Calumet River into the Drainage Canal, 2,000 feet through the tunnel leading from the Lake at 39th street and connecting with the Drainage Canal, and 1,000 cubic feet forced through the opening from the Lake to the North Branch of the Chicago River; therefore be it

Resolved, That the Executive Committee of the Chicago Association of Commerce approves the granting of said increase, provided it shall not become operative until after the

improvements in the channel are completed, namely, a width of 200 feet and a depth of 26 feet, with the exception of the modifications as to width heretofore made by this committee; and with the further provision that the flow of water is to be restricted by the United States Government in the event of undue interference with the navigation interests of Chicago.

I, H. F. Miller, business manager of the Chicago Association of Commerce, do hereby certify that the above is a true copy of a resolution adopted by the Executive Committee of the Chicago Association of Commerce at a regular meeting held on Friday, March 22, 1912.

H. F. MILLER,
Business Manager."

(SEAL)

Letter of Gov. Chas. S. Deneen of Illinois, March 25, 1912.

"I have requested Mr. Isham Randolph, to whom I have handed this letter, to represent the interests of our state at the hearing which he is to appear before you regarding the question of the diversion of water from Lake Michigan for the use of the Sanitary District of Chicago.

Mr. Randolph was a member of the Illinois Internal Improvement Commission and represented our state at certain conferences with the Board of Army Engineers, appointed by the Sixty-first Congress, in its investigation of the improvement of the lower Illinois River and is at present a member of the Illinois River and Lakes Commission.

C. S. DENEEN,
Governor."

Argument on Behalf of The State of Illinois Supporting the Prayer of The Sanitary District of Chicago for a Permit to Take 10,000 *Cubic Feet of Water Per Second from Lake Michigan, April* 3, 1912.

"To the Honorable Secretary of War:

As a preface to the appeal which I am about to make to your reason and your sense of justice, I shall in the briefest way recite a few historic facts.

Lake Michigan in order of magnitude stands third in the roster of the Great Lakes, with an area of 22,326 square miles. This body of water belongs wholly to the United States and is allotted to the several states which bound it as

follows: Indiana, 230 square miles; Illinois, 1,674 square miles; Wisconsin, 7,500 square miles; and Michigan, 12,922 square miles. (See Statistical Abstract of the United States for 1907, page 19.) In these waters, the treaty of Washington, 1871, gave the citizens of Great Britain equal rights of navigation with the citizens of the United States subject to the laws of the State bordering thereon. This treaty terminated by its own limitation in 1881 and thereafter the citizens of Great Britain had no treaty rights in these waters but were by courtesy accorded all the privileges they enjoyed under the treaty. And thus it has been until the promulgation on May 13, 1910, of the now existing treaty.

The history of Chicago is not ancient for only one hundred years have elapsed since the Fort Dearborn massacre. Modern as it is, however, it is crowded with incident. Chicago was incorporated in 1837 with a population of about four thousand. When the great fire of 1871 swept the city, the population was about three hundred and twenty-five thousand. Today, nearly forty-one years after the fire, the population has reached two million two hundred and fifty thousand. The source of water supply for this great city is and has been since its inception, Lake Michigan. For a long term of years that great reservoir was also the receiver of the sewage of the city and it was only when the waters became so foul as to produce disease that an effort was made to safeguard the water supply. The steps which led up to this effort and the details of its successful issue cannot be recounted here. The Chicago Sanitary and Ship Canal was dug and the flow of the Chicago River was caused to turn backward and through that once foul channel, the waters of Lake Michigan are flowing towards the Gulf of Mexico.

The legislation by the State of Illinois which authorized this great work had wide notoriety. The Sanitary District law which went into effect July 1, 1889, was widely advertised; its constitutionality was attacked but it was sustained by the courts. All of this was known to the Congress of the United States and to the executive departments of the Government and from no one of these did there come a protest to a prosecution of the work which was commenced Sept. 3, 1892. That work was prosecuted diligently for eight long years with the full knowledge of every department of the United States Government. The work was visited by Congressional delegations; by Secretaries of War; by Chiefs of Engineers, by officers of the United States Engineer Corps;

and no voice was raised in opposition. Literature describing the work was scattered broadcast. I myself sent out thousands upon thousands of concise reports describing the work. We sought publicity. On the seventeenth day of January, 1900, the dam at the south end of the channel was lowered and the waters of Lake Michigan began to flow southward. At that time, the Sanitary District had expended in creating the work over thirty-three million dollars. The water has been flowing through that channel for twelve long years without let or hindrance from any governmental source with the result that the typhoid death rate of the city of Chicago which in 1891 was 173.8 per 100,000 was in 1910, 13.26 per 100,000. Now you are asked to exercise your great power in restraint of this life giving flow; you are asked to rob humanity to enrich greed.

I am a part of the history of the Sanitary District; for fourteen years and two months, I was its chief engineer, the executive head of its construction, and I am and have been for nearly five years its consulting engineer and I know whereof I am speaking.

The opposition to the withdrawal of water for the uses of the Sanitary District come in great part from the shipping interests on the Great Lakes; the forefront of these is the Lake Carriers Association and of their opposition, I will now speak historically. This opposition first had an opportunity for official manifestation after the appointment of the International Waterways Commission in 1904 (?). I was first confronted by this opposition in June, 1906, when we were notified that a hearing would be given in Buffalo to all parties who wished to be heard in relation to the levels of the Great Lakes. This hearing took place on the 26th day of June, 1906, in the Federal building in Buffalo, and I was sent on to represent the Sanitary District of Chicago and defend its rights as best I could.

The meeting was a very depressing one to me, for I found myself friendless and in the enemy's country. The commission was unfriendly—when I say this I mean unfriendly officially, for in spite of our official differences I had personal friends on that commission, and I believe the official strike did not militate against personal kindness of feeling. The Canadian shipping interests were largely represented and were very hostile. Boston was upon its own dunghill and its opposition was bitter to the verge of brutality. The Lake Marine was there by its officers strongly arrayed against us.

The president of the Lake Carrier's Association, Mr. Livingstone, made an address which disconcerted me greatly. He said that the lowering of the lakes one inch meant to the modern lake carrier a loss of 100 tons carrying capacity and that the certain lowering of the lakes six inches meant a loss of 600 tons per trip, that the average number of trips per season was 23 and the average net earning 50 cents per ton. Then he gave the number of vessels that would be affected and showed an aggregate annual loss of $2,500,000. I came home much disheartened; but as I ruminated on the matter it occurred to me that there was no boat on the lakes that carried 100 tons per inch of draft. I got the Blue Book of American Commerce; scheduled all of the lake boats and computed their carrying capacity and was comforted.

Shortly thereafter the then Secretary of War, Mr. Taft, issued a notice that all who were interested in the question of lake levels would be accorded a hearing before him. Of course the Sanitary District took a hand in this. Its attorney and its chief engineer prepared arguments. I had all the data collected—to refute Mr. Livingtone's statements—in manuscript, but not knowing whether I would have a chance to use it I did not have it printed with the rest of my argument. The hearing was set for January 14, 1907. I went down a couple of days ahead of time to see if I could gather any new facts, that would help me. Through the help of our Congressman, James R. Mann, I secured an advance copy of the report of the International Waterways Commission, and therein—sure enough—was the Livingstone address without quotation marks and therefore adopted by the commission as its own. When my turn to address the secretary arrived I delivered my address as far as it was printed, and paused. The secretary addressed me thus: 'Mr. Randolph, have you seen the report of the International Waterways Commission?' I replied, 'Yes, Mr. Secretary, and I thank you for asking me that question, for it gives me an opportunity to call your attention to grievous misstatements in that report.' Then I read as follows:

'A Review of Some Questions Raised in the Report of the International Waterways Commission.'

On page 3, paragraph 24 of the report of the International Commission, I note a certain misleading statement into which the commission has doubtless been betrayed by the Lake Marine Interest, as I heard the assertion upon which it is based made to the commission in Buffalo on June 26th last by Mr.

Livingstone, president of the Lake Carriers Association. It is this:

'In the modern vessel each inch of increased draft adds about 100 tons to the carrying capacity.'

With this text they go on to state that:

'To lower the water surface six inches is to reduce the capacity of the vessel about 600 tons.'

Then they reason further:

'If the freight rate on ore be taken at 55 cents per ton, exclusive of the cost of loading and unloading, and the number of trips during the season at 22, there appears a loss of over $7,000 for the season for each vessel. The number of vessels navigating the Great Lakes which draw 19 feet or more is 417 and their tonnage is 1,514,414 tons, which is about three-quarters of the total tonnage of the lakes. It is a conservative estimate that the loss to navigation interests resulting from a reduction of six inches in the depth of water is $2,500,000 per annum, which capitalized at 4 per cent. amounts to a loss of $62,500,000.'

This is a terrific showing—but is it true. Here is the crux of the discussion.

I have made such a study as the sources of information available to me have admitted of and I find this:

The American Lake Marine comprises the following numbers of vessels of the several gross tonnages named:

265 vessels between 1 and 2 thousand tons.
158 vessels between 2 and 3 thousand tons.
77 vessels between 3 and 4 thousand tons.
99 vessels between 4 and 5 thousand tons.
31 vessels between 5 and 6 thousand tons.
23 vessels between 6 and 7 thousand tons.

---

652 vessels total.

At the time I heard President Livingstone make this statement, I accepted it as authoritative, but later upon reflection, I grew skeptical and so I began to investigate and give my results:

I found that in the American Lake Marine there were at the time he made this assertion 153 vessels, between 300 and 400 feet long. Maximum length in this class 396 ft. x 45 ft. That there were 111 vessels between 400 and 500 feet maximum length in this class of 488 ft. x 52 ft. beam. That there were 42 vessels between 500 and 600 ft. long and the maximum length of this class was 588 ft. x 58 ft. beam.

Of the maximum in each class there were:
1—396x45.
2—488x52.
6—580x58.

For the sake of argument, let us figure all of each class as of the maximum of that class—a manifestly improper thing to do—and see what results we get.

396x45 gives us 41.2 tons per inch of depth.
488x52 gives us 59.4 tons per inch of depth.
580 x58 gives us 78.8 tons per inch of depth.

153 vessels multiplied by 41.2 equals	7,303.6 tons.
111 vessels multiplied by 59.4 equals	6,593.4 tons.
42 vessels multiplied by 78.8 equals	3,309.6 tons.
	17,206.6 tons total

for 1 inch in depth. 17,206.6 multiplied by six, gives us 103,239.6 tons for that depth. Multiply 102,239.6 by 22 trips and we get 2,271,271.2 tons as the year's loss of tonnage. This at 55 cents amounts to $1,249,199.16. Capitalize this sum at 4 per cent. and we get $31,229,979.00, instead of $62,500,000.00. Now let us try the inaccurate but approximately reasonable method of taking for these vessels an average between their maximums and minimum dimensions and see where we come out.

153 vessels 348x48 equal to 39.1 tons per inch,
or 5,982.3 tons.
111 vessels 444x48 equal to 47.3 tons each per inch,
or 5,250.3 tons.
42 vessels 540x56 equal to 70.8 tons each per inch,
or 2,973.6 tons.
14,206.2 total tons for one inch in depth.
14,206.2 multiplied by six (inches) equals 85,237.2 tons.
85,237.2 multiplied by 22 (trips) equals 1,875,218.4 tons, which, at 55 cents, amounts to $1,031,307.12, which sum capitalized at 4 per cent. amounts to $25,784,253.00 a considerable saving over $62,500,000.

It is proper before leaving this subject, to state that at least one vessel 600 feet long and 58 feet wide has been launched by the Chicago Ship Building Company and the same company is now building one 605 feet long x 60 feet. The tonnage per inch of depth of the first is 81.5 and of the second 85 tons. There is not a vessel in sight on the lakes having a carrying capacity of 100 tons per inch.

But why discuss any such proposition at all in view of the

report of a Board of Government Engineers that remedial works at the east end of Lake Erie will restore navigable depths at a cost of only $796,923.00; and when further it is demonstrable that a proper control of the waters of Lake Superior by works now installed, will remedy the whole evil? It may be urged that the existing works are inadequate, but it cannot be denied that they can be made adequate by a very inconsiderable additional expenditure.

As to the propriety of Canadian and U. S. Governmental advice to a city in any State of this Union as to the manner in which it shall dispose of its sewage and conduct its municipal engineering, I must leave the people of the several states to express their opinions.

ISHAM RANDOLPH.

Washington, D. C., Jan. 12, 1907.'

When I finished reading, the vice president of the Lake Carriers Association demanded that I withdraw the statement. I asked why I should. He replied, 'Because you are a civil engineer and don't know how to figure tonnage.' I asked how they figured it, and not one of them could tell me. I wrote out the formula, and giving it to General Ernst, who sat beside Mr. Taft, asked him if it was right. He examined it and said it was right. Then Harry D. Goulder, attorney for the Lake Carriers, came over and asked me to withdraw the report. I asked 'Why.' He said: 'Your sources of information are incorrect.' I showed him the book from which I got it. He said: 'That is authentic,' and sat down.

I have my copy of that report of the International Waterways Committee but it is a rare document. It was recalled and expurgated before re-issue.

Now the Chicago Sanitary and Ship Canal was built in conformity with the Illinois Sanitary District law passed in 1889, which requires that there shall be a dilution of 20,000 cubic feet per minute for every hundred thousand of the population draining into the channel. The work was predicated upon a population of three million and the flow required would therefore be 600,000 cubic feet per minute or 10,000 cubic feet per second.

What the view of prominent members of the United States Engineer Corps were in regard to this requirement is clearly shown by the following quotation from a report on a fourteen foot waterway from Chicago to St. Louis:

'The board does not condemn the present plan of taking 10,000 cubic feet per second, believing as it does that some

such amount will be needed to protect the lives and health of the people of a great city and of a populous valley, but it invites attention to the the fact that if a much larger amount be taken it will be necessary to construct remedial works elsewhere and that these are, or should be of an international character. It is led to make this remark by the attitude of the Illinois legislature and other principal advocates of this enterprise which is that a fourteen foot waterway is only a beginning and that a much deeper channel ultimately should be constructed, which means that a larger volume must be taken from Lake Michigan. It is the opinion of the board that the sanitary reasons for the abstraction of water so far exceed and overshadow the commercial reasons that the amount should be strictly limited by the sanitary necessities of the case. It is possible to fix a limit to the future growth of Chicago. In a future not a remote larger amounts of water may be needed for sanitary purposes, and channels deeper than fourteen feet will then become practicable in the open alluvial portion of the Illinois river.'

The signers of this report were: O. H. Ernst, Colonel Corps of Engineers; W. H. Bixby, Lieut. Col. Corps of Engineers (now General and Chief of Engineers); and Thomas L. Casey, Major Corps of Engineers.

From the report of the International Waterways Commission, dated December, 1906, I quote as follows:

'Any discussion of the preservation of Niagara Falls would have been incomplete without some reference to the Chicago Drainage canal, which was designed to divert from the southern end of Lake Michigan 10,000 cubic feet of water naturally tributary to the falls. A discussion of the effect of such diversion upon water levels, and consequently upon the navigation interests of the Great Lakes and of the St. Lawrence valley, could find no proper place in the Niagara Falls report. In recommending the allowance of 10,000 cubic feet per second to the Chicago Drainage canal the commission ignored those important questions. It is believed, in so doing, that it was accepting a general tacit agreement that some such amount was required to protect the health of Chicago, and that that city should have it without further question, whatever the effect upon navigation might be. It is believed also that the amount was all that Chicago asked or desired. It turns out that in this latter respect it was mistaken. Plans are on foot at Chicago which calls for a much larger amount at present and for amounts in the future to which no limit is assigned.

The commission has collected a large amount of information upon the subject and has held public hearings at Buffalo and Chicago, but its investigations are not entirely completed. It will at an early date submit a full report upon the subject.

(Signed) O. K. Ebner, *Chairman;*
George Clinton, *Member;*
E. E. Haskell, *Member.*'

There is so much that is pertinent and illuminating in the reports of the International Waterways Commission that I am tempted to quote therefrom in extenso but will resist that temptation and quote only a few passages. From their report transmitted Jan. 4, 1907, page 6, paragraph 19, I quote:

'In the expenditure of $40,000,000 for the drainage canal the people of Chicago, with its population of 2,000,000, incurred a burden equivalent to that due to an expenditure of $1,600,000,000 by the United States, with its population of 80,000,000—that is, enough to build eight or more Panama canals. It was a very serious effort and has commanded the admiration and sympathy of all observers. The diversion of 10,000 cubic feet per second from Lake Michigan affects other interests adversely, but these interests have withheld their opposition, seeming to believe that some such amount was necessary, and apparently willing to contribute their share to protect the lives and health of the people of a great city. The plans calling for that amount have been under public discussion for some years. Although withholding formal approval, the Federal authorities have taken no steps to prevent their execution. Congress has called for a plan and estimates for an improvement of the waterways connecting with it, the scope of which is fixed by that amount. There appears to be a tacit general agreement that Chicago needs or will need about 10,000 cubic feet of water per second for sanitary purposes and that the city should have it without further question.'

From the same report, page 15, (r) and (s) of the summary:

'(r) The diversion of 10,000 cubic feet of water per second at Chicago will render practicable a waterway to the Mississippi River fourteen feet deep. Any greater depth must be obtained by the abstraction of more water from Lake Michigan and at the expense of the navigation interests of the Great Lakes and of the St. Lawrence valley.

(s) The effect upon Niagara Falls of diverting water at Chicago is of secondary importance when considering the

health of a great city and the navigation interests of the Great Lakes and of the St. Lawrence valley, but it is proper to note that the volume of the falls will be diminished by the full amount diverted at Chicago.'

And paragraph 43 on page 16:

'A careful consideration of all the circumstances lead us to the conclusion that the diversion of 10,000 cubic feet per second through the Chicago river will, with proper treatment of the sewerage from areas now sparsely occupied, provide for all the population which will ever be tributary to that river, and that the amount named will therefore suffice for the sanitary purposes of the city for all time. Incidentally it will provide for the largest navigable waterway from Lake Michigan to the Mississippi river which has been considered by Congress.

We therefore recommend that the Government of the United States prohibit the diversion of more than 10,000 cubic feet per second for the Chicago Drainage canal.

All of which is respectfully submitted.

From Report, dated December 1, 1907, Appendix C, page 17, letter addressed to Secretary of War:

'The situation is fairly stated by the company, and the request seems to us reasonable. It is consistent with the recommendations contained in our report of March 19, 1906, which reads as follows, viz.:

"If the falls are to be preserved it must be by mutual agreement between the two countries. As a step in that di-

rection we recommend that legislation be enacted which shall contain the following provisions, viz.:

(a) The Secretary of War to be authorized to grant permits for the diversion of 28,500 cubic feet per second, and no more, from the waters naturally tributary to Niagara Falls distributed as follows:

	Cu. ft.
Niagara Falls Hydraulic Power & Manufacturing Co...	9,500
Niagara Falls Power Company.....	8,600
Erie Canal or its tenant (in addition to lock service)...	400
Chicago Drainage canal	10,000

(Signed) O. H. ERNST,
Brigadier- General, U. S. Army, retired, Chairman;
GEORGE CLINTON, *Member;*
E. E. HASKELL, *Member.*'"

It is proper to state here that the preceding part of this brief was prepared prior to my leaving Chicago on March 25th, to attend the hearing which you accorded to the Dominion of Canada and its shipping interests two days later. At that time I had no knowledge of what transpired before you on Feb. 28, last. As I journed to Washington, I had an opportunity to read a stenographic report of that hearing which informed me of certain erroneous and surprising statements made then, which in the interest of truth and in behalf of the State of Illinois, I must take notice of.

The hearing which you held on the 27th instant was also fruitful of assertions which I must refute if I can and I believe I can.

Carrying Capacity of Vessels.

First, I will deal with the claims made for capacities for lake steamers, which are palpably in error. I had hoped that the outcome of the hearing on Jan. 14, 1907, a certain phase of which I have hereinbefore recited, had put that question beyond the point of argument, but my hope is disappointed. The carrying capacity of any maritime craft is gauged by the amount of water which she displaces. Each cubic foot of fresh water weighs 61¼ lbs. I will make my illustration fit the lake carriers, with which this whole discussion arose.

The class of boat doing business on the Great Lakes is adopted for its utility and not its 'symmetry of mould'; it approaches very closely to the lines of a monster watering through; its horizontal section, save for the taper at stem and

stern—to make it ship-shape—is a parallelogram. To get at the area of this horizontal section, we multiply the length by the breadth and then take nine-tenths of the result as the approximately true area. Having the area and desiring to know the displacement each inch of depth, we multiply the area by 62½, divide by 12 (to get the weight per inch) and then divide the result by 2,000 lbs. The quotient will be the number of tons that the vessel will carry per inch of depth. An approximately accurate formula is:

Length a x breadth b divided by 42.7.

Revised Statute, Section 4150, of Navigation Laws, lays down clearly the rules for determining length, depth and width for computing tonnage. There is no vessel afloat on the Great Lakes that carries in excess of 82.2 tons per inch. I read on page 380 of the stenographic report of the hearing before you this statement from Mr. William Livingstone, president of the Lake Carriers Association: 'We figure our modern boat, that our 600 footers, that we average 113 tons per inch.' I trust that this is a stenographic error, for I heard Mr. Livingstone testify, under oath, on May 24, 1909, that the capacity of such boats was 80 tons per inch. This question is of importance because of the effort to show enormous losses to the shipping interests by reason of lowering the lakes. I considered it so important that I have figured out the tonnage capacity per inch of every American vessel of 400 feet length, or over, on the Great Lakes; and as an appendix hereto I submit a schedule giving all of these boats, with their tonnage, length and width as defined by statute and with the names of their owners. With this schedule I submit drawings of the lake carrier J. K. Sheadle, built in 1906, that you may see how to apply the statutory rules for determining dimensions. The data for the schedule submitted is offered by the Blue Book of American Commerce for 1910, a compilation for which Mr. Eugene T. Chamberlain, Chief of the Bureau of Navigation, Department of Commerce and Labor, is responsible.

The Hydrographs of the Great Lakes.

Mr. Secretary you are looking for the truth in regard to this controversy. You must found your ruling upon the bed rock of truth, or else that ruling will be like the house founded upon the sand; when the rain of criticism descends and the winds of opposition blow and the floods of indignation come

the decision will fall 'and great will be the fall of it.' Is not your confidence in the integrity of the U. S. Engineer Corps sufficient for you to accept their exhibit of recorded facts? Are they not men who will not lie? I am willing to rest the case of the State of Illinois on their facts—not on their opinions—I tie to their facts and many times I dissent from their opinions.

I submit herewith a hydrograph prepared by the 'United States Lake Survey' showing 'Monthly mean water levels of the Great Lakes from Official Records of 1860 to Date.'

To examine that exhibit, start in with Lake Superior, the level of which is about 22 feet above Lake Huron, into which it empties and it is, therefore, above and beyond the influence of the draft made upon the lakes by the Sanitary District of Chicago.

Note that its low water period came in 1892-3 and that it afterwards rose and kept well above the low water mark until April, 1911, when it fell 4½ tenths below the lowest previous water, but recovered and rose 1.65 feet. Now drop down to Lake Michigan and note its lowest water December, 1895, four years before the Chicago Sanitary Canal was opened. Note how it rose after that period and never has gotten as low since, although it showed a drop responsive to the reduced out-flow of Lake Superior, in 1911. Now note Lake Huron conditions, which are practically synchronous with those of Lake Michigan.

Now drop down about 8 feet to the surface of Lake Erie and note its lowest stage in November, 1895, a stage which it fell below by half a tenth of a foot, in February, 1902, but ever since then it has been well above that low water mark. Now drop down about 327 feet to the level of Lake Ontario and note its low water in November, 1895, and then see that ever since the opening of the Sanitary District the lowest stage reached by that lake has been nine-tenths of a foot above the low water of 1895, and that the lowest stage reached in 1911 was one foot and one-tenth above the low stage of 1895.

Mr. Secretary, weigh well this showing made by the loyal men of your own department, and then believe contrary showings from sources less well authenticated if you can. This brings me up to a discussion of arguments advanced by your honored Chief of Engineers, General William H. Bixby. My association with him, usually in opposition, extends over a number of years. We have been frank with each other and as he once expressed it to me 'we have played the game with

our hands on top of the table.' On Jan. 8th last I received a letter from him enclosing a copy of a letter which he had given to 'a few members of Congress.' The closing sentence of this letter reads, 'Moreover none of these copies was distributed until after I had shown you personally the blue prints and told you about them, as I considered that you especially were entitled to early notice of their interests.'

I will address myself now to the closing sentence of his enclosure to me. 'The end of 1912 will probably see these four lakes lower than in 1895-1896 (the lowest yet known since 1860) and more than 1.5 feet lower than their average of the past 51 years.'

Now I want to call your attention to what I consider a serious omission on the General's part when he promulgated his conclusions. He did not permit himself to consider the causes of lowering in the 13 years preceding 1900.

If you will consult Document No. 159, Fifty-sixth Congress, Second Session (a report prepared by Lieut. Col. J. W. Raymond, Mr. George Y. Wisner and Mr. Alfred Noble on Deep Waterways between the Great Lakes and the Atlantic) you will find this statement on pages 297-298: 'The low water level of Lakes Michigan and Huron has been lowered about 1 foot during the past 13 years by natural and artificial deepening of the St. Clair and Detroit Rivers.' That, mark you, was before one drop of Lake Michigan water had trickled into the Chicago Drainage canal. There is one foot of the 1.5 for which General Bixby contends, accounted for without making Chicago accessory to the recession. I shall take up this particular phase of the discussion again under the head of interlake channels.

Opposition to Granting the Permit Sought in the Sanitary District.

In taking up a discussion of the objections to the granting of the permit sought, I feel that I have to deal with honest conviction on the part of many of the objectors that the fears which they express are founded upon what they believe to be facts. In the front rank of this honorable class stands the Dominion of Canada, so ably represented by Hon. David Mullin, K. C. There is other opposition which is factious and still other which is purely selfish and which endeavors to mislead you by specious and fallacious allegations. It is not incumbent upon me to differentiate between these classes of ob-

jectors and to distinguish them by name. I think, however, that before I finish this discussion you will know who I think they are. although I name no names.

Dominion of Canada, Represented by Hon. David Mullin, K. C.

In conversation between this gentleman and Mr. J. C. Williams, counsel for the Sanitary District of Chicago, to which I was a party, Mr. Mullin said that he had been called suddenly in this case and had had scant time for preparing his discussion of it. This acounts largely for his use of so-called facts which he had no chance to verify, and I am sure he would not like to be held responsible for their accuracy. On page 4 (typewritten brief) he asserts that there has been no acquiescence by Canada in the granting to Chicago of 10,000 cubic feet per second. I have hereinbefore quoted at some length, from the reports of the International Waterways Commission. These reports are public documents submitted contemporaneously to both the United States and Canada. They were in the nature of information and advice to each Government, concurred in by the joint advisers. There is in this case something stronger than the old doctrine of consent given by silence. These great powers were informed and advised and no dissent came from either. If in their wisdom they thought the Sanitary District ought to be restrained, it was their duty to take action and save that District the cost of outlays they were prepared to make. Their joint servants received no instructions to protest against the taking of this water by the Sanitary District, and, assured by their silence, that District has gone on spending millions of money, raised by taxation, in perfecting its system along the lines of the original project. He takes up the question of water power and through misinformation states that the Sanitary District development at Lockport is 56,000 H. P., so I will go at some length into that question.

I do not think he quite appreciates the absurd conclusion he ascribes to the International Waterways Commission when he quotes from their reports of January 4, 1907 (see page 24), to the effect that 800 c. f. s. to be taken from the Calumet river and 300 c. f. s. taken from the Chicago river will be added to the 10,000 c. f. s. sought to be taken from Lake Michigan, thus making the total outflow '11,000' c. f. s. This water is measured at he discharge end of the canal and every cubic foot coming from any other source than the lake reduces the

direct abstraction from the lake. Hence, under his theory, using the terms he gives, only 8,900 c. f. s. would come from the lake reservoir direct.

In the matter of carrying capacity of lake vessels he falls into the same trap that so embarrassed the International Waterways Commission in 1907. Some president of a marine association must have told him that these vessels carry 110 tons to the inch of draft. Either this or the figures are based on the starved ton that coal dealers sometimes send to their retail customers.

On page 17 he takes up the traffic at Sault Ste. Marie and shows again that somebody has given him wrong information. I have with me a "Statistical Report of Commerce Passing Through Canals at Sault Ste. Marie, Michigan and Ontario, During Season of 1910, Prepared under Direction of Col. C. McD. Townsend, Corps of Engineers U. S. Army."

Let us contrast Mr. Mullin's statement with Col. Townsend's report. First, Mr. Mullin, "The Canadian Canal 31,531,036 tons and the American Canal carried 15,602,873 tons." Col. Townsend reports American Canal 25,927,661 tons, Canadian 36,435,557 tons. American per cent. 42, Canadian, 58. American Canal open 224 days. Canadian Canal open 248 days. This difference in time opening for traffic is not explained, but the deduction is that the Canadian Canal carried 10,507,896 tons more freight than the American Canal and was in commission for 24 days longer than the American Canal, or reduced to percentages 16 per cent. more freight or 10¼ per cent. more time. It seems certain that the longer navigation period through the Canadian lock had more to do with its larger usefulness than did its four inches greater depth over the miter sill.

On page 27 he has something to say about the water supply and sewage disposal of Toronto. Here his misinformation is second-hand. Toronto does filter its water supply. It is discharging raw sewage into its harbor; it proposes, unless its authorities have changed their plans since receiving the report of its water supply commission—of which I am a member—to discharge its raw sewage after removing a small percentage of coarser solids by screening, directly into Lake Ontario, without treatment. Constant reference is made to the reports of the International Waterways Commission.

Mr. Secretary, I urge you to get that full set of reports and read them carefully. Of course, Mr. Secretary, I do not presume to argue the propositions of law put up to you by the

learned King's Counsel. My knowledge of law is only that absorbed by thirty odd years of contaminating association with learned lawyers.

Among those who came to support Mr. Mullin's contention was Mr. R. W. Reford, president Montreal Board of Trade. On page 184 I read this statement made by him: 'The principle upon which application for further diversion of water is made is unsound and if conceded further demands from other municipalities may be such that to grant them would destroy navigation in a commercial sense.' The Maker of the Universe has so constructed the region around the Great Lakes that there is but one locality along the shore line of these 'unsalted seas' where water can be made to flow by gravity from one water shed into another water shed, and Chicago occupies that strategic position; hence there can be no ground for Mr. Reford's fears 'that other municipalities will make' menacing demands. Next came Mr. Allen, president Shipping Federation of Canada, owners of two ships, the 'Victorian' and the 'Virginia.' He says 'we send these ships out at drafts ranging from 27 feet 5½ inches to 26 feet and they went out in six trips with a vacancy of 8,340 tons and 27 feet 6 inch draft, the ships drawing 26 feet 6 inches.' This language needs interpretation for my understanding in view of what he says in the previous page (190) 'we get down to 29 feet, not 27 feet, as stated by Mr. Meredith.' Now if they had 29 feet of water, why did they load to only 26 feet 6 inches when they claim to load to the last inch of draft? Mr. Francis King, representing the Richelieu and Ontario Navigation Company (page 158) sets up a plea for certain excursion boats which 'shoot the chutes' at various rapids, much to the enjoyment of sensation-loving excursionists. I do not know whether Mr. King lays most stress on the thrills which run down the back-bones of the excursionists, or the earnings of the boat owners; but Mr. Secretary, I ask you if you will weigh those thrills against the pangs of fever-stricken Chicagoans, or the losses in those two boats against the loss of investment made by the people who, to save their lives, have put $65,000,000 into the Chicago Drainage canal. I want to set down to Mr. King's credit that where he gives the tonnage of boats that he lists, he has not followed Lake Carrier precedents.

Now as to the claims of lessened harbor depths at Toronto. Look at your hydrographs of Lake Ontario and decide on the credibility of the witnesses. It cannot help you there but I

believe the U. S. Engineers. And what I advise about Toronto, I advise about Milwaukee, Toledo, Cleveland and all of the lake cities and towns which have protested against issuing this permit, because of the lessened depth in their harbors. Now there is in Mr. Mullin's brief, on page 13, a table giving what it is now the actual lowering, what they think it will be with an abstraction of 10,000 cubic feet per second and what they thought it would be for 14,000 cubic feet per second. They say they know what it is under conditions of flow as they have existed and as they do exist.

Now every officers of the Corps of U. S. Engineers who has been stationed in Chicago for ten years past knows that the flow through the Chicago river has greatly exceeded the volume named in the permit of the Secretary of War. Prior to the opening of the power plant at Lockport the whole flow passed through the controlling works and by their measurements, constantly noted and recorded, we kept a reliable record of the flow. That information is among the records of the Sanitary District. Since the opening of the power plant, in the fall of 1907, the question of discharge has been more complicated and the records less reliable. Two years ago, in trying to arrive at the natural low water flow of the Illinois river, I had to determine the flow in the Sanitary canal, which I did by meter measurements taken at Romeo. I found the flow to be slightly in excess of 7,000 cubic feet per second. These gentlemen have assumed a state of facts which do not exist and they find an actual lowering of four and three-tenths inches at Montreal. Note the three-tenths inch—very accurate work that. In view of their lack of dependable knowledge, what reliance can you place upon their determinations for 4,166 cubic feet per second or 10,000 cubic feet per second, or 14,000 cubic feet per second? How great is your faith?

The Water Power.

It has been directly charged that the motive back of this request for a larger flow of water is that the increased flow may develop water power.

This has become a hoary charge which I have had to meet before Congressional committees and otherwise.

I was employed by the Sanitary District of Chicago on June 7, 1893, to build its drainage canal—that and nothing more.

At first the construction problems absorbed my thought and my activities. As by organization and training the work

itself ceased to demand my exclusive thought, I came to realize that some day there would be a man-made river rushing down the declivity from Lockport to Joliet and that a great potentiality would be running to waste which ought to be conserved for the benefit of the people, whose taxes had paid for the great work. I outlined a plan for this conservation and submitted it to the Board of Trustees, with the result that I was set down upon and told that I was employed to build a drainage canal, not to look after water power. I was sat down upon, but my upholstering is not of the kind that makes sitting a luxury for the sitter and I persisted in my purpose of having that water utilized and the power works at Lockport are today a monument to that persistency.

Now the cost of building that channel from Robey street, Chicago, to the controlling works was $33,000,000. The cost of giving the Chicago River dimensions adequate for the flow of 480,000 cubic feet per minute (8,000 cubic feet per second) has been $11,000,000. The pumping plant and the 39th st. conduit for the delivery of 120,000 cubic feet per minute (2,000 cubic feet per second) to make up the total of 600,000 cubic feet per minute required to dilute the sewage of 3,000,000 people has cost approximately $2,000,000, or a total of $46,000,000, without the slightest provision for water power. Now the dependable fall at the Lockport power site is 34 feet. A flow of 10,000 cubic feet per second falling 34 feet will yield 30,900 horse power on an efficiency of 80 per cent. Now to get this water to the controlling works cost $46,000,000, or $1,488.67 per horse power. The interest on this cost, at 5 per cent., is $74.43 per annum. The net earnings per horse power will not exceed $25 per annum. Do business men make those kinds of investment? To utilize this power, three more miles of channel had to be built and the power plant erected, which was done at a cost of approximating $4,500,000.

I was before the Rivers and Harbors Committee of Congress in regard to the Calumet-Sag channel, which the district desired to build to reverse the flow of the Calumet River, just as the Chicago River had been reversed. I was asking for 4,000 cubic feet per second, my estimates on the cost of such a channel were nearly $12,500,000. I was asked by a member of the committee if my real purpose in seeking to get this water was not to create water power with it? My answer was in the form of a demonstration of the value of the power set over against the cost. Horse power to be obtaine 12,360 net, cost $12,500,000; cost per horse power

$1,011.32. The answer conclusively removed the mercenary motive from my plea.

Now this all pertains to the Sanitary District, a creation of and therefore subordinate to the State of Illinois, which I represent in this controversy. The water—which is so necessary to the health and life of Chicago, is flowing past the wheels at Lockport and dropping in the next 62 miles 100 feet. One hundred feet of fall 10,000 cubic feet of water per second; after deducting 12 feet for necessary slope there remains 88 feet of head, 10,000 feet of water with a net potentiality of 80,000 horse power. The Sanitary and Ship Canal of Chicago was not created for gain, but for health and life, and incidentally commercial navigation. As a natural consequence of this great construction a great potentiality is running to waste down the Illinois River. Does not true conversation demand that it be used for the service of man?

Mr. Mullin, in his able presentation of the cause of the Dominion stated that this water would produce four times more power if flowing through the interlake channels and the St. Lawrence, than it would at Lockport. He had knowledge of the creation at Lockport only and not of the potentialities that lied down stream from it.

With all the vast possibilities of power between the head of the Niagara River and Lake St. Peter now available and unavailed of, I would ask Mr. Mullin if his opposition to the use of about 4½ per cent. of these potentialities by Illinois does not savor of selfishness, does not even suggest the dog in the manger, a position which I am sure he would not unwillingly occupy, either for himself or his people.

On page 75, chapter 16 of the report of the preservation of Niagara Falls which the President transmitted to Congress Aug. 21, 1911, the following statement is found:

A volume of 210,000 with a descent between the dead line and the upper gorge of 220 feet has a potential of over 5,000,000 horse power.

Now the drop from Lake Erie to Lake Ontario is, roundly stated, 327 feet, so that there is 107 feet not accounted for in this statement, I assume that 92 feet of the 107 feet may be useful head and on that assumption I find, using an efficiency of 80 per cent., upwards of 1,700,000 horse power running to waste or a total potentiality for 210,000 cubic feet per second of water dropping from Lake Erie into Lake Ontario of over 6,700,000 horse power. Of the other millions of horse power going to waste in the drop from Lake Ontario to Lake St. Peter, no mention is made.

Conditions at Montreal.

We have had a luminous illustration flashed upon us by our Canadian friends of the embarrassment which may result from discussing grave questions without having a basis of authenticated facts to sustain our position.

My knowledge of conditions in the Montreal harbor is meagre, gleaned from the Encyclopedia Britanica, Reports Nos. 100 and 110 of the U. S. Hydrographic Office and from maps studied in the Congressional library. As the results of these studies I have formed conclusions, not rock ribbed, but tentative. First, the ascertaining of the velocity of streams is a determination involving cross section, slope, roughness of channel and some judgment must be exercised in selecting the coefficients used in the computations. But with the velocity once known and the average width of the stream the depth due to any given volume of flow is easily ascertained with approximate reliability. Knowing the velocity in feet per second and the width of the stream, multiply the one by the other and divide the volume of flow per second by the result of the multiplication. The result thus found will be the depth due to that volume of water flowing with the known velocity.

The Encyclopedia tells us that the St. Lawrence Channel below Montreal permits ocean vessels drawing 30 feet at low water to reach the city docks. That after the river freezes over there is a local rise of 10 feet.

A map entitled 'Montreal Harbor from Latest Canadian Charts,' scale 1/12.000 published at Admirality, 8th of July, 1908.

Data on this Map.

River dredged to 30 feet below the low water of 1897. The width dredged is 450 feet with greater width at all curves. The river has a very great fluctuation and is usually at its highest in the second week of May and at it lowest from about the middle of September to the end of November. Its average height above datum of soundings is: In May, 8 feet; June, 6 feet; July, 5½ feet; August, 3½ feet; September, 2½ feet; October, 1½ feet; November, 2½ feet. The rise in level from Longue Point to Lachine Canal is 1.74 feet.

I scaled on this map the width opposite La Salle avenue, which seemed to be about an average width and found it 4,650 feet from city shore line to sand shoals opposite.

U. S. Hydrographic Report 100, gives datum as extreme low water of 1897 which was 13 feet and 7 inches on the old lock sill of the Lachine Canal at Montreal and it is 1½ feet below ordinary low water.

This is seemingly reliable data, but without knowing velocities no deduction could be made. This information was furnished by another Admirality map on which velocities are shown at certain points. These velocities are in knots per hour (Kn):

Just below Victoria Bridge 8 Kn.

Opposite DeLarimer av. 6½ Kn.

Opposite Montreal st. railway 5½ Kn.

Now a nautical mile or knot is 2,029 yards or 6,087 feet, hence 5½ Kn equal 334,785 feet per hour, or 9.3 feet per second.

By the approximate rule that I have given, used with the data available, I get 4,650 feet by 9.3 seconds gives 43,245 cubic feet; 10,000 cubic feet per second divided by 43,245 gives a depth of 23/100 of a foot. Conditions at Montreal are very much complicated by the inflow from the Ottawa River a few miles above the city.

The Bixby Report on Illinois Waterway.

Mr. Mullin, K. C., representing the Dominion of Canada, quoted with approbation a statement which appears in the report of a board of engineers, of which General Bixby was chairman, in which they state that 1,000 cubic feet per second was sufficient for all of the needs of navigation. This report wronged the interests and the rights of the State of Illinois so greatly that I asked for a hearing on it before Mr. William H. Taft, President of the United States. This request was granted and on April 13, 1911, General Bixby joined me and we argued the questions at issue before the President. As a result of that discussion the President wrote Governor Deneen the following letter:

The White House,
Washington, April 17, 1911.

Hon. Charles S. Deneen, Governor of Illinois:

Sir—I have your communication of April 15, 1911, under advisement. The project for a navigable waterway from Lake Michigan to the mouth of the Illinois River, and thence via the Mississippi to the Gulf of Mexico, is one of national importance and commands my sympathy.

In view of the work already accomplished by the Sanitary

District of Chicago, an agency of your State, which has constructed the most difficult and costly stretch of this waterway and made it an asset of the nation; and in view of the fact that the people of Illinois have authorized the expenditure of $20,000,000.00 to carry this waterway sixty-two (62) miles further to Utica, I feel that it is fitting that this work should be supplemented by the Government and that the expenditures recommended by the Special Board of Engineers on the waterway from Utica to the mouth of the Illinois River be made upon lines which, while providing a waterway for the nation, should otherwise benefit the State to the fullest extent.

On behalf of your State, there has been no legislative commission with whom the Board of Engineers could negotiate and the board has reported a project for the lower river which, I learn from your letter, is not satisfactory to the State.

In view of this fact, I shall recommend to Congress that the term of service of said board be continued and that it be empowered to re-open the question of the treatment of the lower Illinois River, and to negotiate with a commission hereafter to be created by your General Assembly, and to agree with such commission upon a plan for the improvement of the lower Illinois River and upon the extent to which the United States may properly co-operate with the State of Illinois in securing the construction of a navigable waterway from Lockport to the mouth of the Illinois River in conjunction with the development of water power by the State between Lockport and Utica.

Very truly yours,

WM. H. TAFT.

In conformity with the statement in that letter, the President did, on December 21, 1911, transmit to Congress a message containing this language:

The project for navigable waterway from Lake Michigan to the mouth of the Illinois River, and thence via the Mississippi to the Gulf of Mexico, is one of national importance. In view of the work already accomplished by the Sanitary District of Chicago, an agency of the State of Illinois, which has constructed the most difficult and costly stretch of this waterway and made it an asset of the nation, and in view of the fact that the people of Illinois have authorized the expenditure of $20,000,000.00 to carry this waterway 62 miles farther to Utica, I feel that it is fitting that this work should be supplemented by the government, and that the expenditures

recommended by the special board of engineers on the waterway from Utica to the mouth of the Illinois River be made upon lines which while providing a waterway for the nation should otherwise benefit that State to the fullest extent. I recommend that the term of service of said special board of engineers be continued and that it be empowered to reopen the question of the treatment of the lower Illinois River, and to negotiate with a properly constituted commission representing the State of Illinois, and to agree upon a plan for the improvement of the lower Illinois River and upon the extent to which the United States may properly co-operate with the State of Illinois in securing the construction of a navigable waterway from Lockport to the mouth of the Illinois River in conjunction with the development of water power by that State between Lockport and Utica.

This brings us up to the importance of—

The Lakes to the Gulf Deep Waterway.

The need of this waterway has been felt for generations and its inception goes back to the early days of the Nineteenth Century, when it was so strongly advocated by Albert Gallatin. Chicago has built the most costly link in this waterway and the whole Mississippi Valley is interested in its completion. Its need is great now and that need will be vastly accentuated after the opening of the Panama Canal.

The President evidenced his interest in this project when he sent the following letter to the chairman of the Rivers and Harbors Committee of Congress:

The White House,
Washington, D. C., Dec. 23, 1911.

Hon. S. M. Sparkham, Chairman, Rivers and Harbors Committee:

Sir—In view of the great importance to the whole country of the creation of a waterway from the Great Lakes to the Gulf of Mexico, I call your attention briefly to a consideration not taken up in the section of my message which related to that waterway. The State of Illinois has, by an overwhelming vote of the people, authorized the expenditure of $20,000,000.00 for building of that link in this waterway between the present terminus of the Chicago Sanitary canal—near Lockport—and Utica on the Illinois River, a distance of sixty-two miles. The opponents of the project have questioned the suf-

ficiency of the amount—authorized by the people of the State—to pay for the work planned by the Internal Improvement Commission of the State. These estimates, however, have been checked by the board of engineers, whose appointment was authorized by the Sixty-first Congress, Second Session, and were by them considered sufficient to cover the cost involved. See H. R. Document No. 1374, pages eight and ten. On page eleven, this statement is found.

'Should the State of Illinois be unable to complete the locks suggested by the board, or the bridges required by navigation, the United States might then properly undertake to complete these parts of the project, but as the authorized appropriation of $20,000,000.00 by the State is considered sufficient for all work above Utica, no estimates are submitted for these parts.'

I concur in the belief of the board as expressed above and feel that the Congress should endorse the project; and further in view of the character and ability of the men who have reported upon the project, I think that the United States runs small risks in guaranteeing any sum that this link in the project may cost in excess of the $20,000,000.00 that the State will provide. This work should progress in time with the improvement of the upper Mississippi, the Missouri and the Ohio rivers. Its importance warrants congressional action in its support.

(Signed) WILLIAM H. TAFT,
President.'

Now there can be no higher use of a natural resource than the saving of human life. Quotations made hereinbefore show how the water that is being abstracted from Lake Michigan is fulfilling the highest mission of saving life, and when you consider that it will at the same time serve to make a commercial waterway, you see how justly we can demand it, both in the name of humanity and of navigation. Canada has an outlet to the sea from the Great Lakes by a 14 foot channel. Should America have less to her southern sea? And be it remembered that this waterway will, when built, be a free channel, free to Canada, free to the world. Canada will need to reach southern ports by the short water route, just as will the citizens of the United States, who dwell in our lake ports.

Mr. James White, secretary Commission of Conservation, opposes the taking of this water for both economic and scenic reasons. Let us first consider the economic side of it. The

volume of water involved in this present controversy is 4 76/100 per cent. of the flow through the St. Clair River with the Lake Huron elevation 581.28 and 4 54/100 per cent. of the flow of the Niagara River. What will this abstraction accomplish? It conserves the life and health of the second greatest city in America. The typhoid death rate of that city in 1910 was 13 26/100 per 100,000; in 1891 it was 173 8/10. It makes a 14 foot navigation from the Great Lakes to the Gulf possible; it will afford 110,000 net electrical horse power. It makes the Illinois River, next to the Columbia River, the greatest producer of food fishes in America. Is not this true conservation? Can it be shown that 10,000 cubic feet of water used anywhere else in the world will do mankind as much good? When we contemplate the aesthetic side of it, our gaze concentrates at Niagara. The beauty and grandeur of that wonderful work of the Great Creator can be preserved by simple engineering construction. I laid a plan for this before the Minister of Public Work of the Dominion of Canada Feb. 13, 1911.

Dr. Pugsley referred this project to Messrs. St. Laurent and Coste with whom I conferred. Their expressed views to me were approving. When I presented my letter of introduction from Mr. Taft to Mr. Fielding, Minister of Finance, his first inquiry was, is there any money in it for Canada? He then said, 'We have to look at these things from the dollars and cents standpoint.'

I told him that the beauty of the Falls could be maintained and at the same time a larger use of water be granted for generation of power.

Confirming this assertion—although it has no reference to the project which I brought forward—I call attention to the fact that on August 21, 1911, the President transmitted to the Senate and House of Representatives a message giving 'Information relative to scientific investigations made by certain officers of the War Department for the preservation of Niagara Falls.'

In Chapter XVI, page 75 et seq., their conclusions are summed up. I quote therefrom:

Provided there be no large increase in up-lake diversions, the possibilities of continued and extended use of power at the Falls are conditioned upon the construction of regulating works in the Niagara River to avoid the wasteful outflow of water of Lake Erie. The injury to the scenic grandeur of the Falls, and the interference with the navigable waters of the

Niagara River and Lake Erie, due to up-lake diversions would be largely obviated by impounding in the lakes a portion of the winter out-flow during the months of December to April, inclusive, enough water may be saved to hold the lakes in a proper and economical level to the betterment of navigation, and yield a surplusage to practically offset diversions at the Falls. This is a practical engineering proposition but as the power companies are beneficiaries they should pay a fair share of the cost.

Here, all that—we as State and Sanitary District officials—have contended for through long years of controversy is admitted as being right in theory and capable of practical development.

Mr. White (I think it was he, I have not his brief to refer to) brought up the question of extravagant use of water by the District for purposes or dilution. If ever there was a long contested question this has been one. Let him scan the 8,000 printed pages of testimony in the case of the State of Missouri vs. The Sanitary District of Chicago and see if he can discover a scientific authority on either side of that great controversy who would admit that 20,000 cubic feet of water per minute was too much to use in diluting the sewage of 100,000 people. It is the habit of both sides of this controversy to appeal to the printed reports of the International Waterways Commission—and it is a good habit too—Mr. White has it. Now that commission employed sanitary experts to advise them; the best men they could find. These gentlemen stated as their second conclusion—

The latest conclusions of sanitary engineers as to the amount of dilution which is required to make sewage inoffensive are that a dilution of 3½ cubic feet per second for each 1,000 persons connected with the sewers as provided in the enactment of the Illinois Legislature of 1889, is as low a figure as it is now possible to state.

Page 51 of report dated Toronto, Ontario, January 4, 1907.

What was, after patient inventigation, determined upon was found to stand the test of 18 years of progressive science.

Objections from the State of Michigan.

Objections from a sovereign state must receive consideration and respect, but it is very hard to treat seriously the plea upon which the objections from Michigan are based. They are in the same super-sensitive category with the charge

raised some years ago that the cold water sent down the Mississippi River by the Chicago Canal was destroying the strawberry crop in Mississippi and Louisiana. In my study of these lake level problems in preparation for these ever recurring controversies, I ascertained as nearly as may be that the state of facts is very nearly as follows:

The discharge through the St. Mary's River is ordinarily 75,000 cubic feet per second. At the time I made my computations the reported flow through the St. Clair River was 206,400 cubic feet per second: 131,400 cubic feet of which must come from Lakes Huron and Michigan. Figured on the ratios of rainfall and area I find that Lake Michigan contributes 48.26 per cent (63.414 c.f.s.) and Lake Huron 51.74 per cent. (67,986 c.f.s.).

Now if Chicago takes 10,000 c.f.s. it leaves the outflow from Lake Michigan through the Straights of Mackinac 53,414 c.f.s. and the changed flow cannot, in my judgment, have an appreciable, or any effect upon the climate of Michigan. However, Congress has imposed upon a Commission of Engineers the duty of determining and reporting to it the climatic changes brought about in Michigan by the work of the Sanitary District. If you mean to wait for the determination of this question until those engineers report, we pray you to spur their action; for they are under your jurisdiction.

Objections from the Illinois Valley.

Sundry objections to granting the plea of the Sanitary District of Chicago until such time as the channel of the Illinois River has been made adequate to carry the flow artificially delivered to it, have been filed by associations and individuals living and owning property in the Illinois Valley. We have no quarrel with these petitioners, in fact there is a basis of reason in their effort to protect themselves through you. They are suffering a burden which they ought not to bear.

The Sanitary District of Chicago is required by its organic act to remove from the Illinois River the dams at Henry and at Copperas Creek. They have never done it and they have never done it because they have bene enjoined from doing it by a court of competent jurisdiction on the petition of the canal commissioners of the State of Illinois. You need not be burdened by the details of this family row. The dams ought to be removed—they are not needed for navigation—as is reported by a board of engineers of the U. S. Engineer

Corps, and they are a positive harm to the low lands along the river by holding the water at high and harmful elevations. These elevations are not great, but they are harmful.

Now, Mr. Secretary, do you feel called upon to punish one side or aid the other to this controversy? With these dams removed there would be peace in our camp and if you can see your way to their removal, we would regard you as a great pacificator.

Arbitrary Demand for Changed Methods of Sanitation.

The demand made upon the Sanitary District that it change its method of treating sewage after it had expended $66,000,000 is analogous to requiring a public service corporation which has, at great cost, put in a steam plant of type best known and approved at the time of its installation—triple expansion compound condensing engines, etc.—to discard the whole equipment while its usefulness and efficiency is unimpaired, and substitute therefor steam turbines.

The project of the District is designed to meet the requirements of a given population by dilution methods. When that limit of population is reached, remedial works will have been provided to care for the excess known to have accrued. There is a limit fixed to the amount of water that may be used by two governing considerations—

First—The volume which may safely be taken from Lake Michigan.

Second—The volume which may be discharged into the Illinois Valley without damaging the property adjacent to the stream.

Owner's Risk.

I do not know whether my belief based upon a natural perception of justice or whether it comes to me as the result of an aforesaid legal contamination, but I believe that when an investor with full knowledge of a certain risk that he runs, by reason of what he knows will come about as the result of certain plans of others which he has every reason to believe will be carried out, that he has no recourse at law; no action against the person or persons, corporation or municipality, which, by carrying out plans which were well known to be matured before he made his investment, cause him to lose profits which he hoped to secure.

It seems to me that the vessel owners are just in the condition of this investor. Prior to 1900 there were but 40 boats on the Great Lakes with keel length over 400 feet and all of these, except four, were less than 450 feet. The first of these to be built was the S. S. Curry, 432x45, built in 1893, when lake navigation was limited by the depth over the miter sill of the Weitzel Lock, which was 17 feet with the upper pool at 601.9, lower pool 584.4; in 1895 the Victory, 452x48, was built. Since 1900, 210 of the larger class boats have been built.

Inter-Lake Channels.

Lakes Superior and Huron are connected by the St. Mary's River Canal, the Sault Ste. Marie locks and the St. Mary's River. In 1881, when the Weitzel Lock was opened for traffic, I find the statement that with the water at elevation 601.9 in the upper pool and 584.4 in the lower pool, there were 17 feet of water over the miter sill, hence its elevation must have been 567.4. In 1881 the high level of Lake Huron 582.3. In 1887 the Poe Lock was connected; with lower miter sill at elevation 562.1 and a calculated depth of water over it of 22 feet; when this depth obtained the level of the lower pool must have been 584.1. This lock was completed in 1896, four years before the opening of the Chicago Drainage Canal. Prior to this lock being put into service the Government had been improving the lower St. Mary's River to a depth of 20 feet, greatly diminishing the slope in the St. Mary's River and thereby reducing the depth of water over the lower miter sills of the two American and the one Canadian lock. The statistical report of Lake Commerce through the St. Mary's Falls Canal for the year 1910 states that safe draft of water through the locks was only 18.4, which indicates an elevation of 580.5 for the lower pool, three feet and nine-tenths lower than the elevation of 1881.

A glance at the hydrograph for 1910 shows the extreme high water of 1910 to be just 580.5 and the mean for the months of open navigation of 580.25. To all intents for the uses of navigation the slope in the lower St. Mary's River is, therefore, wiped out. The next connecting channel is the St. Clair River, which begins in Huron and ends in Lake St. Clair.

Since the year 1900, the work of deepening and widening the interlake channels has gone steadily on. What has been accomplished in that direction is briefly but luminously set forth in Bulletin No. 20, Survey of the Northern and North-

western Lakes, published by U. S. Lake Survey Office, Detroit, Michigan, 1911, under authority of the War Department.

The present improvement dates from the project of 1867 for the construction of a straight ship channel 300 feet wide, protected by dikes, extending from deep water in the mouth of the South Pass to deep water in Lake St. Clair. This canal was formally opened July 25, 1871, although the channel had been used by vessels in the season of 1870. The original plan provided for 13 feet depth, which was modified in 1872 to 16 feet, and in 1886 to 18 and 20 feet. The river and harbor act of June 13, 1902, provided for two separate channels for up and down-bound traffic, by the excavation of a new channel 20 feet deep and 300 feet wide along the west side of the old canal. This west channel was opened to navigation September 3, 1906.

The existing canal consists of two channels above mentioned, extending from the mouth of the South Channel into Lake St. Clair a distance of 17,460 feet. For a distance of 7,221 feet at the upper end, the two channels are separated by a sand dike 100 feet wide, revetted by sheet piling, and the old or east channel is enclosed on its east side by a similar dike 50 feet wide. The old east channel is 292 feet wide between the dikes and the west channel is 300 feet wide. Below the dikes the two channels are combined with a uniform width of 750 feet. The depth of the channel is 20 feet.

Lower Detroit River. At Ballard's Reef there are occasional fluctuations in depths of from 3 to 5 feet, produced by high easterly or westerly winds which respectively raise or lower the water level at the west end of Lake Erie and similarly affect the level of the lower river. Display stations to show the depth existing at Ballard's Reef are maintained at Sandwich coal dock, at Smith's coal dock near Rogue River, and at Elliott Point about opposite the foot of Bois Blanc Island. During the season of 1910, the lowest mean depth in the river for any month was 19.7 feet, this being at Ballard's Reef.

Approved projects provide for the deepening of the present channel to 21 feet for a width of 600 feet from the head of Ballard's Reef to Bar Point, and for the same depth for 800 feet width from Bar Point to deep water in Lake Erie; also for a second channel (Livingstone Channel) of 22 feet depth and 300 feet width from Ballard's Reef to Bar Point, passing to the west of the Bois Blanc Island, and for the same

depth for 800 feet width from Bar Point to deep water in Lake Erie. The latter project will not be completed before 1912.

The conditions of the improved ship channels of the lower river, as existing at the beginning of the season of 1911, are described below.

Ballard's Reef. The channel is 600 feet wide, nad its center line is marked by the Grosse Isle South Channel Range. The present improved depth is 19.5 feet, with work in progress to secure 21 feet depth south of the junction with Livingstone Channel and 22 feet depth north of this junction. On account of these improvements, navigation will be restricted to 300 feet width during the season of 1911, and such portion of the channel will be marked by gas buoys with additional spar buoys when necessary.

Lime Kiln Crossing. The channel is 600 feet wide and 21 feet deep. A line 150 feet from the west side of the channel is marked at the north end by two lighted targets, one on Texas Dock and the other on the Canadian shore; and at the south end by two lighted targets placed on stakes driven in the water near the east short of Bois Blanc Island. A line 150 feet from the east side of the channel is marked at the north end by two lighted targets on the Canadian shore south of Texas Dock.

Amherstburg Reach. The channel is 600 feet wide, and 21 feet deep, except for an area about 100 feet square in its west half at the head of Bois Blanc Island where the least depth is 20 feet; the center line is marked by two light towers on Elliott Point. Just south of the intersection of Amherstburg Reach and Hackett Range, and east of the channel, is an anchorage basin 2,000 feet long and 300 feet wide, with 19.5 feet depth, marked on its easterly limit by four red spar buoys.

Hackett Range. The channel is 600 feet wide and 21 feet deep, except of an area of about 500 feet long and 100 feet wide in its east half abreast of Elliott Point, where the least depth is 20.5 feet; the center line is marked by two light towers at Amherstburg.

Bar Point Shoal. The improved channel through this shoal is 600 feet wide and 21 feet deep to the Detroit River lighthouse. For an additional 400 feet width to the westward there is 21 feet depth to deep water in Lake Erie in a straight channel passing to the west of the lighthouse. There is also a channel of 800 feet width and 22 feet depth to deep water in Lake Erie passing to the east of the lighthouse.

The Treaty.

Article V of the Treaty plainly recognized the recommendations of the International Waterways Commission in making the amount of water which may be taken on the Canadian side for power purposes as thirty-six thousand cubic feet per second.

For power purposes within the state of New York, it permits the use of water up to twenty thousand cubic feet per second. The allotment to the Sanitary District was evidently regarded as res adjudicata.

Article VIII clearly defines the uses for which water may be taken and gives their order of precedence.

(1) Use for domestic purposes.

(2) Uses for navigation, including the service of canals for the purposes of navigation.

(3) Uses for power and irrigation purposes.

And further safeguards the Sanitary District of Chicago by the sentence, 'The foregoing provisions shall not apply to or disturb any existing uses of boundary waters on either side of the boundary.'

In other words, the limitations of the Treaty were not intended to be retroactive. The Sanitary District, proceeding under a definitely and widely known plan, had been in actual operation for ten years and five months nearly, before the ratifications of the Treaty were exchanged.

I am firm in this view, because it is unthinkable that men worthy of citizenship should neglect the conservation of the lives of the people of their land and only give a care to the commercial interests of a few.

The State of Illinois is before your judgment seat because 40 per cent. of her people are charged with reducing the level of the Great Lakes. The quotations that I have made from official documents of this government show that under the direction of the United States Engineer Corps, by order of congress, work has been done in these interlake channels which has caused a reduction of lake levels vastly greater than has resulted, or can ever result, from the work of the Sanitary District of Chicago. The bulletin for the northern and northwestern lakes for 1905 showed a flow of 206,400 c.f.s. through the St. Clair River with Huron at elevation 581.40; the bulletin for 1911 showed a flow of 210,000 c.f.s. with Huron at elevation 581.28, that is, with a lake level reduced 12/100 of a foot the flow increased 3,600 c.f.s. These conditions are no

secret. During General Alexander McKenzie's term, as chief of engineers, I asked why he should object so to what we were doing when so much greater damage was being done to lake levels under his direction. His reply was, 'What I am doing is by order of congress.' On Dec. 9, 1909, I had this matter up with General Marshall, then chief of engineers. He said that he believed we would lose our lake level case; but he said, further, that he 'did not see why the government should make such a stir about what the district is doing when its own work is doing so much more to lower the lake levels.' He cited the lowering of the St. Mary's River and consequent diminished depth over miter sills on the Sault Ste. Marie locks resulting from improving the channel. But he said the remedy by control is simple and easy. Right here I will say that it has been a source of infinite satisfaction to me to deal with the members of the United States Engineer Corps who have ascertained and preserved the facts essential to an intelligent discussion of these matters. They have been frank and courteous with me, concealing no fact within their knowledge which has a bearing upon these discussions. They regard these facts from a viewpoint different from my own and my effort now is to have you see the merits and equities as I view them.

Mr. Secretary, none of the protestants who have filed objections or appeared personally before you, has proved, or can prove, that they have been damaged. They have presented what they fear they may suffer, not what they have suffered.

Now, I would not leave a doubt in your mind as to what Illinois wants.

The question has been raised—For how long a time is this water wanted?

As long as water runs down hill or floats a boat, Illinois wants this water. She wants it for the health and life of her people; she wants it for her own water-borne commerce and for that of her sister states; she wants it for the power that it will yield; she wants it for the fish that it will produce to feed all the people; she wants it now, henceforth and forever.

Now, Mr. Secretary, can you attach more importance to the desire of a few score people to secure large interest on their investments than to the claims that two and one-quarter million people have upon the use of their investment of $66,000,000—not for gain, but for health and life?

I have confidence that the call of humanity will prevail with you over the clamor of the captains of marine industry for more gain. We have spent our millions to preserve human life. They are piling up millions as an outcome of the expenditure of the people's money, in making deep channels between the 'unsalted seas.'

THE STATE OF ILLINOIS,
By ISHAM RANDOLPH,
Commissioned by Governor Charles S. Deneen to appear for the State."

EXHIBITS WITH BRIEF

OF THE

STATE OF ILLINOIS

IN BEHALF OF

The Sanitary District of Chicago.

STATUTORY LENGTH, BREADTH, DEPTH & HEIGHT OF VESSELS.

Revised Statutes, Section 4150.

"The registry of every vessel shall express her length and breadth, together with her depth and height, under the third or spar deck, which shall be ascertained in the following manner:

The tonnage deck, in vessels having three or more decks to the hull shall be the second deck from below; in all other cases the upper deck of the hull is to be the tonnage deck. The length from the fore part of the outer planking on the side of the stern to the after part of the main stern-post of screw steamers and to the after part of the rudder-post of all other vessels measured on the top of the tonnage deck shall be accounted the vessel's length The breadth of the broadest part on the outside of the vessel shall be accounted the vessel's breadth of beam. A measure from the underside of the tonnage-deck plank, amidships, to the ceiling of the hold (Average thickness) shall be accounted the depth of hold."

United States Lake Survey
MONTHLY MEAN
WATER LEVELS OF THE GREAT LAKES,
FROM OFFICIAL RECORDS
1860 to DATE.

Letter of Approval by C. W. Wright to President Taft, March 26, 1912.

"I write to call your attention to an international opportunity in conservation of water supply.

It might well be presented to the Canadian Commission appearing before Secretary of War, Mr. Stimson, this week, and other interests there represented at the same time. I mean the holding back the waters of Lakes Michigan and Superior during the winter months which will keep the waters of all the lakes at the proper level during the open season for shipping; also permitting Chicago the required amount of water for the sanitary canal. Hoping this will be of interest to you and other conservationsists, I am

CLERIAN M. WRIGHT,
2109 W. Polk St., Chicago, Ill."

Letter of Approval by State Water Survey of the University of Illinois, March 28, 1912.

"Owing to the limited time I did not have an opportunity to speak in behalf of the request of the Sanitary District at the hearing on February 28th. I, therefore, request the privilege of making a brief statement.

The Illinois State Water Survey has been analyzing the waters of the Illinois river for a number of years. Our investigations show that the dilution at the present time is none too great, and should the flow be decreased we are certain that a nuisance would result during parts of the year. We, also, have been in close touch with the work being done by the Sanitary District and feel that they are acting in good faith, in their experiments to determine the proper method of disposing of the sewage of the increasing population of Chicago.

It is the business of the State Water Survey to make investigations which will enable the people of the State to have a pure water supply, and it is our belief that the sewage of Chicago must be diverted from the Lake, and that the curtailment of the amount allowed would work a hardship on the citizens of Chicago.

Our observations throughout the State have brought to our attention the fact that the last two years have included the periods of the lowest water in the Mississippi river as

well as in the Great Lakes. The effect of withdrawing 10,000 cu. ft. per second of water through the drainage canal will have an inappreciable effect in lowering the level of Lake Michigan as compared with the lowering that is being produced by enlargements in the channel of the Detroit river carried out by army engineers. Statements were made that Lake Superior, which cannot be affected in the least by the drainage canal, is lower than it has been for years. Likewise the Mississippi river, even below the outlet of the Illinois river where it is augmented by the drainage canal, has, during the past year, reached the lowest stage in many years.

We sincerely hope that after careful consideration you will see fit to grant the petition of the Sanitary District, which desires to take only one-twentieth of the flow from the Great Lakes. It is our belief that any lowering of the Lake Michigan level which this withdrawal might cause can be counteracted by the construction at the outlet of Lake Huron, of wing dams instead of dredging the channel as is now the practice.

EDWARD BARTOW,
Director State Water Survey."

Letter of Approval by Federation of South End Civic Bodies, March 28, 1913.

"The portion of Chicago most concerned in the matter before you, relating to the diversion of additional water from Lake Michigan, is the southern portion of the city known as the Calumet region, lying south of 87th street. Although, Mr. Secretary, you have indicated that the discussion should relate mainly to the alleged interference with navigation that might result from the permit, I am sure that the question of human life and sanitation will not be completely ignored on the same idea that a messenger in an automobile, charged with the delivery of a message at the quickest possible time, would feel justified in swerving from his most direct course to avoid running down a troop of children.

In order that the people of the Calumet region shall benefit from the Chicago Sanitary Canal, the additional diversion requested is necessary, under the state law, to properly dilute the sewage which will be emptied into the main drainage canal by the Calumet-Sag Canal, a supplementary channel now under construction.

This district comprises a population of upwards of 200,000 people larger than that of any other city in the state save

Chicago itself. A most unfortunate condition now obtains in this section owing to a delay of many years in building the Calumet-Sag Canal. Over a million dollars was recently spent in building the 95th street sewer system, which drains a large part of the District through a ten-foot sewer which has its outfall near the mouth of the Calumet river. About two miles distant, and receiving this sewage when southerly winds or other conditions cause the flow in that direction, is the intake of a large water tunnel just completed at an expense of some $6,000,000, which conveys this effluent back to the homes of the people in the guise of drinking water. Thus our people are compelled to pay $7,000,000 for the privilege of drinking their own filth, this endless chain being forced upon us by the injunction suit of the United States against the Sanital District of Chicago, which prevented the construction of the canal which our district had had every reason to expect for many years, and in expectation of which our various drainage and water plants were planned.

We, therefore, earnestly request the granting of the permit, Mr. Secretary, for the reason that the health and very lives of our people are at stake, which is a matter of far greater importance than any real or fancied injury to navigation. We urge the full permit. If this for any reason seems inadvisable, we must earnestly request a temporary permit for a period long enough to attend to the sewage disposal in some other way, so that in the mean time we may not continue to suffer this unexpected and intolerable nuisance.

The difference in the lake levels will not be the full result of 10,000 cubic feet diversion, but only about half that amount. The present permit allows about half the requested diversion, so that where a difference of six inches has been mentioned the real difference will be only three inches. We submit that this is too small a margin to be seriously considered in a navigation proposition. No navigation worthy of the name can afford to do business upon such a difference.

We submit that the city of Chicago is entitled to keep its house in order in the manner that seems best to its own people and that it is presumptuous for any foreign interest to attempt to dictate the sanitary policy of this city. If there may be an injury to navigation upon a difference in lake levels of three inches, the compensation for that damage is threefold: controlling works, deepening the channels or using less draft. The measure of the damage is the cost of the least expensive of these methods. But we contend that no

material damage can follow the additional diversion requested.

On the other hand this diversion makes possible a great and inestimable addition to the navigation of the Great Lakes and connecting waters. Instead of injuring navigation, it adds a navigable belt around Chicago and the additional project provides what Captain Marshall in the U. S. Engineer's report 1890 states as follows:

'The terminal facilities as far as possible access to Lake Michigan is concerned of the Calumet river and connected chain of lakes for a large system of commodious docks and wharves and harbors (needing only deepening by dredging) in public waters of the United States, point irresistably to the Calumet region as the proper terminus of the proposed waterway from Lake Michigan to the Mississippi river.'

To all these additional facilities Canada will have access equally with the United States. This connection with the Gulf of Mexico leading directly to the Panama Canal will give interior America and Canada the full benefits of this great artery of trade opening in addition to the teeming population of the Mississippi valley the inestimable value to transportation and commerce of free access to the ports of the world.

In conclusion we urge that as against the alleged damage to navigation of a difference of three inches in water levels is offset the sanitation of our people and the construction of channels that without the sanitation feature would not be built, costing as they do upwards of seventy millions of dollars, but which when completed will give the objectors the benefits of the lakes to the gulf waterway and the Panama Canal, the two greatest waterway projects in the world, both of which built and paid for by the United States of America.

HENRY W. LEE, C. E.,
Consulting Engineer, Federation of South End Civic Bodies, Chicago, Illinois."

Resolution of Approval by the Federation of South End Civic Bodies, March 29, 1912

"Herewith I submit brief on behalf of the Federation of South End Civic Bodies of Chicago, Ill., in connection with the hearing before you relative to the permit requested by the

Sanitary District of Chicago to divert 10,000 cubic feet per second of water from Lake Michigan.

HENRY W. LEE, C. E.,
Consulting Engineer, Federation of South End Civic Bodies, Chicago, Ill."

"Whereas in the year of 1903 the General Assembly of Illinois passed an act enlarging the corporate limits of The Sanitary District of Chicago and providing for the drainage of a part of the added territory by said Sanitary District by means of a canal through the Sag Valley, and

Whereas the territory so annexed has been taxed for such purpose from that time until the present, and

Whereas thereafter the Internal Waterways Commission, composed of representatives of the governments of the United States and the Dominion of Canada, reported to the President of the United States recommending the terms of a treaty to be entered into between the two governments which proposed treaty contained a provision that The Sanitary District of Chicago be allowed to extract from Lake Michigan, for sanitary purposes, as much water as should be necessary, not to exceed ten thousand cubic feet per second, and

Whereas thereafter The Sanitary District of Chicago applied to the Secretary of War for a permit to reverse the flow of the Calumet river according to plans which provided for the diversion from Lake Michigan of fourteen thousand cubic feet of water per second, which application was on March 14, 1907, denied by the Secretary of War, and

Whereas The Sanitary District of Chicago, for the purpose of meeting the objections urged by the War Department, has since made further investigation of the problem of disposing of the sewage of the Calumet District, including the southern part of the City of Chicago, which investigation involved the expenditure of large sums of money, and as a result of such investigation the engineers engaged therein deem it absolutely necessary to reverse the flow of said Calumet River to prevent the pollution of Lake Michigan, but find it possible to effect said reversal of flow by diverting from Lake Michigan not more than ten thousand cubic feet per second, and

Whereas application was presented to the Secretary of War for a permit to carry on said work according to the opinions expressed by the War Department from time to time, which application was approved by Major Thos. H. Rees of the Corps of Engineers assigned to the District of Chicago, and

Whereas it is of vital importance to the health of the people of Chicago that this work be carried on without further delay, and

Whereas it has heretofore been held by the Judge Advocate General of the War Department that the Secretary of War has jurisdiction of the subject matter involved in the application for permit made by The Sanitary District of Chicago and the right to issue such permit, and the plans of The Sanitary District of Chicago have been approved by all the engineers having knowledge thereof and interested in the proper solution of the problems of sewage disposal in the City of Chicago and environs,

Now, Therefore, Be it resolved that the Secretary of War be, and he is hereby respectfully urged to grant said permit applied for by The Sanitary District of Chicago, and

Be It Further Resolved that the governor of Illinois, the Mayor of Chicago, the President of the Board of Commissioners of Cook County, Illinois, the Mayor of Blue Island, the United States Senators and each member of the House of Representatives of the United States Congress from Illinois are hereby respectfully requested to use their good offices for the securing of such permit."

Letter of Alfred Noble, Engineer, of New York City, April 2, 1912, to the Attorney of The Sanitary District and Presented to the Secretary of War March 30, 1912.

"You have requested me to express opinions on the following points:

1. Is it practicable to compensate for an increased diversion through the Drainage canal from 4,000 cubic feet of water per second to 10,000 cubic feet per second, by obstructions in the natural outlets of the Great Lakes so that the natural levels of the lakes may be maintained?

2. Assuming that the population of the Sanitary District will be 3,000,000 in 1920, and that the sewage from this population would be sufficiently diluted for sanitary purposes by a supply of 10,000 cubic feet per second, is it practicable to provide the works for the partial purification, as designed and estimated for by the Chief Engineer of the Sanitary District, in time to provide for the subsequent increase of population?

3. If the existing permit to divert water from Lake Michigan were revoked, would it be practicable to provide for the sewage satisfactorily?

In reply to your first question, I have to say that exact compensation, etc., effective at all points along the line of naviga-

tion, is probably impracticable, but I am decidedly of the opinion that substantial compensation, involving no material loss to any interests, navigation or other, is entirely feasible. The obstructions might be, for the most part, simple dikes or embankments, not expensive in character, supplemented in places by movable obstructions of no great extent. Such obstructions in the Niagara river would raise the levels of Lakes Erie, St. Clair, Huron and Michigan, and the St. Mary river below the falls, not precisely in the same proportion as the lowering resulting from the diversion, but closely enough for all practical purposes. It seems clear that the best results would be given by obstructions which would raise Lake Erie slightly above its natural level, with perhaps not quite full compensation in Huron and Michigan. Since the effect on any of these lakes of withdrawing the additional amount of water would be only about 4 inches, it seems probable that compensation could be effected to within an inch, by the obstruction suggested. Similar works at the principal rapids in the St. Lawrence river would maintain the natural levels of that river at all points above Montreal, and of Lake Ontario.

In reply to your second question, I am of the opinion that the constructions proposed can be provided as rapidly as required.

In case of the revocal of the existing permit, as contemplated by your third question, it would be necessary to discharge the sewage directly into the river and lake, which course experience has shown to be dangerous. The works necessary for the purification of the sewage to such a degree that the effluent discharged into the river and lake would be harmless would require several years to construct.

ALFRED NOBLE,
Consulting Engineer."

Letter of Approval by Federation of South End Civic Bodies, April 5, 1912.

"Kindly accept the enclosed as supplementary to my brief filed with you on behalf of the Sanitary District of Chicago. If necessary, it might be filed on behalf of the opposition, because of 'flooded Canadian lands,' the facts showing that the relative level of Lakes Ontario and Superior have changed in eight years since 1900 with higher relative level at Lake Ontario instead of lower, as alleged.

I have believed that you will welcome the facts and these are so simple and so conclusive, that it would be a breach of duty to neglect to send them.

HENRY W. LEE, C. E.,
Consulting Engineer, Federation of South End Civic Bodies, Chicago, Ill."

"The enclosed tables are from the report of the International Commission for 1910. The difference of levels between Superior and the other lakes below it are shown in parallel columns.

The average for eight years preceding and eight years following 1900, when Chicago drainage canal was opened shows variations of +.043, —.069 and +.107 for Michigan, Erie, and Ontario, respectively below Superior. This is not based upon estimate or guess or approximation, but upon actual facts, reports for sixteen years from the highest official sources, averaged for an equal period before and after the diversion at Chicago.

The results show that both Michigan and Ontario are relatively higher as regards Superior than before the diversion, although Erie is —.069, average for the second eight year period.

This proves that the mean average fluctuation is about an inch and that it is variable plus and minus, and that the difference is too small to be seriously considered in connection with navigation, other variations constantly off-setting and far overwhelming this negligible item.

The allegation of three or six inches or other change in levels is disproved by the facts and the records, the only true criterion."

Letter of Approval by David R. Forgan, Pres. Nat. City Bank of Chicago, to Pres. Taft, May 1, 1912.

"I have been asked to call your personal attention to a matter of importance to the City of Chicago in which the Association of Commerce is deeply interested.

The Sanitary District has made application to the Secretary of War to be allowed an increased flow from Lake Michigan from 4,167 cubic feet per second to 10,000 cubic feet per second. The Secretary of War has had a hearing in which the Sanitary District, navigation interests, and the Dominion of Canada have all been represented. The briefs in the case have been referred by the Secretary of War to Genral Bixby for analysis and report.

Now, to put the matter plainly, the members of the Association of Commerce who are in charge of this matter are afraid that the inclination of General Bixby, and also of the Secretary of War, will be simply to view the whole matter from the standpoint of navigation, and not give due weight to the consideration of the vital question for Chicago of its sanitation, and they wish me to request of you that, if pos-

sible, you give the matter some personal, or cabinet consideration when the proper time comes.

This I respectfully ask you to do in the interests of fairness in a rather complicated matter.

DAVID R. FORGAN,
President."

Letter of Approval by John V. Farwell to Pres. Taft, May 8, 1912.

"The Association of Commerce of Chicago whose public spirited work in this city and elsewhere I am sure you are familiar with, through Mr. Wheeler and others who are well known to you, has been deeply interested in the question of increased flow of water from Lake Michigan into the Sanitary District Canal.

Application, as I understand it, is now before the Secretary of War, to allow the District to increase the flow from 4,167 cubic feet per second to 10,000 cubic feet per second.

The Dominion of Canada and some shipping interests have been against this increase, whereas, nearly all Chicago interests are in favor of it.

Believing it to be a case to be viewed not only from the standpoint of navigation but from that much more important one, the health of millions of people living in Chicago and along the line of the Canal, the Association of Commerce were in hopes that you might be able to give the matter some personal attention, or have it brought before the Cabinet for thorough consideration before final decision is reached.

From what I can make out the Sanitary District was not very well represented by the best obtainable legal counsel in making arguments before the Secretary of War.

JOHN V. FARWELL,
President."

Letter of Approval by Secretary of the Treasury Franklin McVeagh to Secretary Stimson, May 27, 1912.

"Ever since the Cabinet meeting when Secretary Fisher urged upon your attention the deep interest of Chicago in the question of water for its drainage system, I have felt that I did not sufficiently accent my approval of the urgent representations which the Secretary of the Interior then made.

And at this rather late day I want to make it perfectly clear to you that I am profoundly impressed by the vital interest which Chicago has in your decision. It may well be that the present drainage system cannot be permanent; but a claim to that effect is recent. We started in with the full expectation that we had a permanent method of drainage, wholesome and unobjectionable from every point of view. It is only later that questions have been raised which seem to point to the necessity of another system of sewage disposal. But, Mr. Secretary, that is a tremendous engineering job and an exceeding financial job. And there are great complications which make obstacles of a most serious nature to any change of system. And, therefore, it must take time to do this—if it is ascertained that it must be done eventually. It is not easy for Chicago to raise sixty millions of dollars or a hundred millions, as this may require. We have spent sixty millions on that drainage canal. Of course, we can throw that away. But it is a serious thing to throw sixty millions away. And it is another very serious thing to raise sixty or a hundred millions, because the Constitution of Illinois restricts, in the most rigid manner, the bonded indebtedness of municipalities. Altogether this is not purely an engineering question you have to decide now; but it is an economic question. And it is a question of what is fair and just to a city of great size and importance, which is the second city in the country. We are a long way from you and you are a long way from us when you are in New York or in Washington. And we have, therefore, to make our appeal under certain disadvantages to an Eastern man. It is much easier for almost any Eastern man to understand an eastern city than to understand a western city. Moreover, Chicago doesn't have the popular appeal in the East that it has in the West. But to me the appeal of the real interests of Chicago is always most impressive. Chicago never plays the baby act; and it doesn't ask for sympathy. It is a manly municipality, and self-reliant. But it has the great interests of not only itself but of the Middle West in its keeping. And dealing with it is dealing with a very great body of public interests.

Now, if we must change our drainage system give us a chance to do it without, in the meantime, suffering. Of course, if the United States Government had said in the beginning that this drainage system was a temporary expedient we would never have entered upon it; and if now it is but a temporary expedient, then I think we should be patient with it

and give it time to change itself, meanwhile treating it generously so that the city can live throughout the interval healthily and safely.

I am appealing, of course, for my home. And I don't want to deny that. But it seems to me I am appealing rather for a great metropolis that happens to be dependent upon your decision.

FRANKLIN MACVEIGH."

Statement of Lawrence McCann, of Chicago, to Secretary of War Stimson, February 28, 1912.

"Mr. Secretary, I would simply ask that since the city of Chicago is referred to as a corporation, for its people I want to beg of the Secretary and the citizens representing other sections of the country, to understand that in the evolution of a great city and in the development of navigation certain things have arisen which may appear to conflict. But the citizens of Chicago would not perimt for one moment that they should appear to tolerate an evasion of any improvement or of any economy that may be developed; and neither the citizens of Chicago nor the corporation of Chicago through its properly accredited officers will yield in their zeal and in their determination to maintain the highest efficiency for navigation consistent with the preservation of conditions of health and safety in the city of Chicago.

I simply beg of you, Mr. Secretary, to keep in mind that the city of Chicago is made up of honorable people, and that many of the questions submitted today are not creditable, and insinuating that there may be an ulterior purpose and motive. There are none but the purest motives, the motives that inspire men and citizens to maintain pure homes, preserve life, promote health and happiness, and in the consideration of this question I want to beg in the name of the Mayor of Chicago, whom I am here to represent, and the people of the city of Chicago, as distinguished from the Sanitary District, that the question be given the simple and fair consideration which I know the Secretary will give it, and I beg for the Commission of the city of Chicago, that it be permitted to file a brief on this question, for the corporation of Chicago, treating the question of navigation, the question of good faith with the Government in carrying out of every regulation that has been laid down by the Government. As you will remember, Mr. Secretary, I have communicated with you, some months past,

in regard to this matter. These will be carried out in absolute good faith through your representatives and through yourself, and the city will take pleasure in co-operating and carrying out the law. But the city also asks that we be given every consideration in the protection of the health of the citizens of Chicago, until such time as a system may be adopted for sewage treatment as will be acceptable and a fair system, and especially considering that the people of Chicago have spent this great sum of money during a period when it was regarded as the most advanced method of treating sewage, when there were no protests and when it was believed that every step, every effort, and every expenditure was being made with the knowledge, the consent and the approval of the Federal authorities.

I simply ask permission in the name of Chicago to file a brief."

Statement on Behalf of the City of Chicago by Lyman E. Cooley, Consulting Engineer, Mar. 30, 1912.

"On the application of the Sanitary District of Chicago, for a permit to increase the flow into its main channel or outlet by way of the Chicago River and other feeders, and in the hearings relating thereto, the City of Chicago has been represented by the Commissioner of Public Works, Hon. Lawrence E. McGann, acting for the mayor, and by Aldermen Charles E. Reading, L. D. Sitts, W. F. Ryan, and John S. Derpa, acting for the city council, and by their consulting engineer, Lyman E. Cooley.

The City of Chicago, has been and is co-operating with the Sanitary District and supporting its contentions, and it has the most vital concern in the issues before you. The consideration of the subject matter has taken a very wide range and raised many questions, all of which could not be anticipated, and the city feels that it should submit a brief in its own behalf which would go fully into the mreits of the questions involved. But it seems that time cannot be allowed for this purpose. The representatives of the city therefore feel constrained to limit themselves to a statement which shall recite concisely the history of the matter, the position of the city, and re-enforce the position of the Sanitary District of Chicago, and the undersigned has been authorized and directed to prepare and submit such statement.

1. The Sanitary project was matured by the City of Chi-

cago in the years 1885-9 at a cost of about $100,000, under the advice of engineering and legal experts and with the co-operation of the State Board of Health of Illinois and a joint committee of the General Assembly. The city promoted the Sanitary District Act in force July 1 1889, and continued its oversight until the Sanitary District was adopted by the people and actually organized early in 1890. The purpose was to provide a main channel or outlet with necessary adjuncts by which the City, together with other municipalities within the corporate limits of the District, could dispose their sewage under certain conditions as laid down in the organic law. Since its organization the confines of the Sanitary District have been enlarged and the City of Chicago through annexation has absorbed in large part the urban population and now contains 94.5 per cent. of the population of the Sanitary District.

The City of Chicago is endowed with full municipal functions as a part of the political system of the state and could have undertaken the complete solution of the sanitary problem had it possessed the proper territorial limits and the necessary financial resources. The Sanitary District was therefore created for a limited and specific purpose. The city therefore views with the gravest concern any proposition or action which tends to limit or disbar any function or power of the Sanitary District because the burden will thus be shifted in greater or less degree, or wholly, back upon the city, with extraordinary complication and cost beyond the power of the city to meet.

The entire policy of the city and its environs for the past twenty-five years in respect to the sewage system, the park system, the harbor and waterway development and all collateral work, has shaped itself in conformity with the sanitary and ship canal project, and any attempt to change policies and conditions at this time will result in the utmost confusion and cannot be seriously entertained or admitted by our people.

2. The Sanitary and Ship Canal of Chicago was actually constructed across the Chicago Divide between the waters of the Chicago River at Robey street and the Desplaines River at Lockport, with a flowing capacity of 840,000 cubic feet of water per minute, or 14,000 cubic feet per second in round numbers at low water of 1847 in Lake Michigan. A small portion of this channel in the clay between Robey street and Summit was constructed with a preliminary capacity of more than 500,000 cubic feet of water per minute, and under the

law is subject to progressive development with the growth of population and also to complete development within one year after the General Government shall co-operate in the production of a through waterway. The cost of such development is relatively a small item. The channel was actually opened January 17, 1900, in compliance with Section 27 of the organic law and no change affecting the capacity thereof has since been made.

The City of Chicago does not admit any doubt as to the full right and power of the State of Illinois to authorize the particular solution and the method of applying it as outlined in the organic law, and attention is called to the decision of the U. S. Supreme Court in 1906, in the case of State of Missouri v. The State of Illinois and the Sanitary District of Chicago, where the whole subject matter was entered into and affirmatively decided. It is not now competent to raise questions as to the manner of the solution nor in regard to the right to take water to the extent of the capacity of the main channel or outlet, or 14,000 cubic feet of water per second at low water of Lake Michigan.

Under the authority of the state, the Sanitary District proceeded diligently and completed its channel as above stated, and had actually notified the Governor of that fact, before the end of the year 1898, and several months prior to the Act of Congress of March 3, 1899, Section 10 of which has been assumed to give jurisdiction in the premises. The permit issued by the Secretary of War and the Chief of Engineers, U. S. Army, May 8, 1899, does not bear out any such presumption, but is conditioned solely by the capacity of the Chicago River. In no event could the act cited have a retroactive effect.

The right of the United States to conserve the highways of commerce and the easements which it has developed is not questioned, and we assume that the right to take water cannot be exercised in a wilful and frivolous manner and so as to create unnecessary hardship to other interests, and therefore we admit a certain degree of supervision as to the manner in which the water shall be taken. The law of the State of Illinois also states that public waters shall not be entered upon and utilized in such manner as to unduly interfere with their uses for navigation.

In addition to the foregoing Chicago claims a right to 1,000 cubic feet per second by way of the Illinois and Michigan Canal and that such right is both proscriptive and by authority of law.

In view of the circumstances already stated the city is unable to develop properly and fully its contentions respecting the foregoing and it expressly reserves its rights in case they are not admitted.

3. The expenditures by the Sanitary District of Chicago from its organization down to January 1, 1912, have been $68,524,491.16

The expenditures by the City of Chicago for its intercepting sewer system along the lake front of the city have been 6,706,804.37

The total is $75,231,295.53

The same ratio of expenditure extended over the United States would represent about $3,000,000,000, or several times the amount expended by the United States upon its river and harbor system.

The further amounts that must be expended in developing and completing the program will bring the total well above $100,000,000. In addition the park boards have expended large sums and will expend still larger sums in parkways along the city front, which serve to protect the water supply of the city and to transfer the filth producing industries to the back lots. It is further recognized that the large sums required for harbor and waterway development must conform to the adopted program.

4. The waterway policy of the State of Illinois has been established from the beginning. The Sanitary District Act was intended by its promoters as primarily a health provision and an important consideration in its passage was that the same waters that performed the service for Chicago would perform a like service for all the urban population contiguous to the Desplaines and Illinois Rivers. A secondary motive was the contribution which would thus be made to the waterway policy of the state; and the state took good care that these provisions of law should be fully set forth. And from the standpoint of the state the Sanitary District Act is a waterway act in which Chicago is allowed certain rights of sewage disposal, in consideration of its investment. The state further defines its position by contemporaneous act and joint resolution and has since adopted a constitutional amendment by which the General Assembly is authorized to expend $20,000,000 between the end of the drainage canal and the head of the lower Illinois River at Utica for waterway

development and incidental water power. The state policy in this respect is based on the full capacity of the drainage canal or 14,000 cubic feet plus the capacity of the Illinois and Michigan Canal, or 1,000 feet, a total of 15,000 feet. The state recognized that a large volume of water will enable the production of a deep waterway not less than 14, feet, as stated in the joint resolutions of 1889 and 1897, and it is further recognized in the report of 1907, that the larger volume for which the Sanitary Canal was actually constructed will enable a still greater depth through the lower Illinois River.

5. The Association of Drainage and Levee Districts of the State of Illinois represents the lands subject to reclamation in the lower Illinois Valley, some 400,000 acres, and it recognizes the necessity for a deep and capacious channel, with a large and permanent water supply therein for the stability and maintenance of the lower Illinois River as well as for the sanitary welfare of the valley; and they are promoting the removal of the dams in this portion of the river and the development of such channel by dredging in conjunction with the water supply from Lake Michigan for the threefold object of drainage, sanitation and deep navigation.

The Lakes-to-the-Gulf Deep Waterway Association represents all interests in the several states bordering the route between Lake Michigan and the Gulf of Mexico, and this association has adopted a policy as set forth in its last two conventions, 1910 and 1911, for a waterway with a preliminary depth of 14 feet with all structures and rock cuts adapted to an ultimate depth of 24 feet, and the large water supply provided for by the State of Illinois is necessary to the carrying out of such a policy.

6. The water power development by the Sanitary District and by the State of Illinois comes strictly under the rules laid down by the U. S. Supreme Court in the Montello case. The Supreme Court of Illinois held in the case of the suit to test the validity of the Sanitary District Act, in June, 1900, that it would be unreasonable to deny the right to develop water power which was created by other than necessary work, and called attention to the fact that the burden of taxation might thus be mitigated. Under the project of the Deep Waterway Association eighty per cent. of the fall between Lake Michigan and the Mississippi River at Cairo, may be converted into water power and this amounts to about half of what the same water would produce if utilized for the same

purpose in the direction of the St. Lawrence, and not one-fourth as has been stated.*

There can be no objection to the development of such power under public ownership as proposed, and as the incident of other and necessary uses of the water for sanitary and deep waterway purposes. It is a circumstance not to be overlooked that the waters diverted are to be put to all of the three uses recognized in their order in the recent treaty respecting the boundary waters between the United States and Canada, to wit: domestic and sanitary, waterway, and water power. These uses are not alternative but cumulative, and they combine in a justification superior to any separate and distinctive reason.

7. The population of the Sanitary District, by the Federal Census of 1910 was 2,311,810. The contiguous population within ten miles of the water route between the Sanitary District and the Mississippi River was 445,828. The total population in the District and in the valley immediately concerned in the sanitary problem and also in the deep waterway was 2,757,638. Of this population 2,468,450 were urban or in communities of 2,500 people and upwards. The aggregate represents 49 per cent. of the total population of the state and 71 per cent. of the urban population.

The aggregate population in cities of 25,000 and upwards about the Great Lakes above Niagara in 1910 was 2,325,543, or less than the urban population of the Sanitary District and adjacent to the water route in the State of Illinois. The statistics for the minor cities are not yet available and these would increase the aggregate for the lakes. And again, we should add the urban population on the Canadian side, for which the data are not in hand. The total, however, would not greatly exceed the figures given for Illinois. There are other populations in the United States and Canada below Niagara which claim to be affected by the diversion of waters and again there are other populations in the United States below the mouth of the Illinois which are benefited thereby.

It may be said, therefore, that a population nearly if not substantially equal to that outside of Chicago and bordering the Great Lakes above Niagara have an indentical interest in the maintenance of all conditions which favor navigation.

*NOTE: This statement is based on complete development and full utilization by means of dams. Reserving the scenic attractions of Niagara River under the Treaty of 1909 and employing the usual methods of development, the statement in Topic 51 is also true.

It may be said further that such population have a deep and immediate concern in the development of a deep waterway through the State of Illinois and onward to the Gulf of Mexico, and that that deep interest should in truth extend to all the population about the Great Lakes and differ only perhaps in degree. In addition to the above this half of the total has a paramount interest in its life and health, which should be generously recognized by the other half even though minor damage and inconvenience be inflicted. If it is shown later that no actual harm or inconvenience is necessary, then most certainly there can be no valid ground for objection, in view of the tremendous potentialities involved in the diverted water.

8. The effect on lake levels and the damage caused thereby is likely to be overestimated. Causes affecting lake levels are many and show up in continual oscillation, sometimes through a considerable range, and in changes of general level with the seasons in the years, and through a cycle of years. There are no fixed rules to govern the variable effects due to difference in rainfall, vegetal cover, run-off and evaporation, and the individual and collective effects are so incapable of precise definition that it is impossible to deduce a remainder which could be assigned to an unknown cause. The fact of a diversion and the amount thereof would be discoverable only in the new outlet itself, and the valuation of the effects thereof would be purely a deduction from physical data and not a subject of direct observation. Whatever the effect may be, by such amount is lowered the general horizon of oscillation and change. Owing to the variations vessels cannot utilize the depth with the same degree of certainty as though a fixed and invariable plan prevailed, and it may be questioned whether a proper rule of damage can be based on the theory of a change in such plan. In other words, is it not attempted to apply the precision of the rifle to a shotgun problem?

It is to be noted that the natural depths at characteristic localities in the intermediate channels of the lakes were originally from ten to twelve feet and that these depths were increased at various times until a general depth of sixteen feet prevailed, and that between the years 1891 and 1895-6 these channels were deepened by four to five feet and greatly enlarged, and that coincident with the completion of these deeper channels we have the characteristic low water period. It is to be noted further that following the high water of 1886

there has been almost a continuous deficiency in rainfall, amounting to six feet more or less at various lake stations, and this coupled with accentuation of evaporation has produced profound results. It is to be noted also that the Board of Engineers on Deep Waterways, in its report of 1900, recognizes a permanent lowering of Lakes Michigan and Huron by nearly one foot, through a change in the outlet at Port Huron. It may be said further that the report of the International Waterways Commission for 1910 calls attention to the fact that the level of Lake Superior was unwittingly controlled for a number of years by the works of the International Bridge and of the water power companies at Sault Ste. Marie, with consequent influences on the levels of the lakes below, and this fact, though the effects were comparable with those assigned to the Chicago Drainage Canal, seems to have attracted no attention. These several and superior effects seem to have aroused no excitement among vessel interests, nor have they led to any propositions for remedying the same. It is therefore not quite understandable why such supreme importance is attached to the minor effects produced by the diversion at Chicago. The report of the First International Waterways Commission, 1896 (American section, known as "United States Deep Waterways Commission"), gives all obtainable information respecting lake levels prior to 1860, and it appears that the highest water known occurred in 1838, and that the lowest water known occurred nineteen years previously, in 1819-20, and that such low water was from eight inches to one foot lower than the low water of 1895-6. It appears, therefore, that the extreme fluctuation of the lake surface took place within a period of nineteen years, and before inhabitation had changed conditions in the watershed, and before lake channels had been disturbed. The range of fluctuation in Lake Michigan was between six and seven feet.

Had the Chicago diversion begun in 1895-6, contemporaneously with the opening of the deeper intermediate channels and the Poe Lock at the Soo, and when the lake fleet had not developed to these greater depths, it could not have been said that navigation interests were damaged by reason of the fact that the unutilized depths had been diminished by a number of inches. On the contrary, it is known that great loss in vessel property took place as soon as the larger depths were utilized by the greater carriers, and that such damages were without redress because what had been done was in the interest of the common welfare. The new lock at the

Soo authorized some time since and now under construction is to have a depth of 24½ feet, the same as that of the Drainage Canal, or several feet in excess of existing channels, and the policy of producing channels which shall equal such lock depth is already established. In view of this project actually in sight and in process of consummation, is it to be said that vessel interests will be damaged by a diminution in depth not yet utilized and for which no vessel exists? In the progressive deepening of lake channels and that of the harbors which must follow is not the effect of diversion substantially met, and, if not, does it involve more than a nominal increase in cost to meet the deficiency due to such cause?

9. A minor damage or inconvenience may be without redress under the doctrine of "comity among utilities," but that is no sufficient reason for denying the appropriation of public waters to beneficial use when and where the benefits are manifold and contribute in an extraordinary degree to the public welfare. The report of the International Waterways Commission, on the Chicago Drainage Canal, 1907, estimates the damage to be occasioned by the diversion of 10,000 cubic feet per second and the consequent lowering of the lakes by six inches at $1,500,000 per annum, in round numbers. On the other hand, the value from the bettered sanitary condition at Chicago and in the Illinois Valley cannot be estimated in figures; the value of the water highway that is to be produced with the aid of this diverted water is comparable with that of the Great Lakes; the reclamation of the overflow lands of the Illinois Valley is facilitated, and this represents a very large sum; water powers are created under public ownership, and this represents another large contribution to wealth; and again fisheries develop through the greater volume and the enrichment of the waters.

In the ten years between 1896 and 1906, the fisheries of the Illinois River increased from a catch of about 8,000,000 pounds to 22,000,000 pounds and the stream was second to the Columbia, where in fact the fish are the product of the sea. The value of these fish on the shore of the waters was over $770,000, or $11 per acre for all the water space in the Illinois Valley, and this value was doubled by the time the fish reached the consumer or exceeded $1,500,000, and will grow exceedingly with the fuller development of the Chicago program. In other words, the value of the annual fish crop which has come to pass through the carrying out of this en-

terprise exceeds all the damage which it is claimed has been occasioned to the shipping interests on the Great Lakes.

10. A remedy that may be applied so as to conserve the actual uses of water now made and avoid all damage is a complete answer to any objection to the taking of any volume of water that can be applied to other beneficial uses. No one will contend that waters cannot be appropriated if other and prior appropriations and dedications are not unduly interfered with.

The International Waterways Commission has examined a number of remedies, one of which is that of deepening channels and harbors by one foot at a cost of $12,500,000, which would allow the taking of 20,000 cubic feet of water per second, or a third more than the capacity provided for in the channels at Chicago. It is submitted that this cost would be still less if the deepening is part of the program for deeper channels and harbors now initiated by the construction of the new lock at the Soo.

The International Waterways Commission, in its report for 1910, suggests a remedy which it regards as better and sufficient by means of compensation work. It is now engaged in working out the problem connected therewith, and is to report thereon before closing its labor.

It is unnecessary to multiply instances or advance suggestions. Congress has authorized examinations and reports respecting the better control of lake levels and has also authorized examinations and reports based on the theory of utilizing waters diverted from Lake Michigan.

The State of Illinois directly and through its agencies has made a very large expenditure and is prepared to make other very large expenditures, the effect of which will be to produce a great waterway, which will pass to the control of the General Government, under all state laws thus far made and proposed, and the United States will thus be relieved of cost many times exceeding the cost of any remedies that may be required on account of diverted waters. It is felt, therefore, that the United States should raise no question of liability as against the State of Illinois and its agencies on matters beyond their jurisdiction.

11. The international question and the bearing thereon of the treaty of 1909 respecting boundary waters between the United States and Canada will not be entered into at this time. Attention, however, is called to an opinion furnished to the State Department by the Attorney General, Judson Harmon (see Opinions of Attorney Generals, 1895-7), in re-

gard to a boundary water of the United States and Mexico, the Rio Grande del Norte, the navigation of which is expressly guarded by specific terms in the treaty of Guadloupe Hidalgo, between the United States and Mexico. In this case the waters of the stream were consumed in the development of the State of Colorado and the Territory of New Mexico, and in the opinion the rules of international law applicable in such cases are fully set forth.

It appears that the right of the people of a State to develop their resources and opportunities is fundamental, and that the United States cannot qualify by treaty sovereign rights not possessed by it.

12. In conclusion it may be recapitulated:

(a) Under proper and sufficient authority, physically expressed in adequate channels actually constructed and in existence, the right is established to take 15,000 cubic feet of water per second from the Chicago River by way of the main drainage channel or outlet and by way of the Illinois and Michigan Canal.

(b) The Secretary of War and Chief of Engineers, U. S. A., may not impair this right, but shall regulate the manner of taking so that no undue injury shall occur to the navigable channels through which such waters shall pass, as heretofore contrued in permits.

(c) Independent of the questions referred to above under (a) and (b) the right to take the water should not be questioned in view of the enormous expenditures already made, the policies established and the expenditures predicated thereon, and in view of great and manifold benefits as contrasted to minor damage and inconvenience.

(d) Such minor damage as may occur is not irreparable and may be remedied at comparatively small cost, and the taking of waters for beneficial uses under such circumstances is not a subject for objection.

(e) The remedy, if any, is not within the jurisdiction of the State of Illinois and should be applied by the United States in view of the tremendous contribution of the State of Illinois and its agencies to a waterway of national and international importance.

(f) All the points herein referred to can be set forth and established in a brief in full which the time available has not permitted.

On behalf of and for the City of Chicago.

(Signed) LYMAN E. COOLEY,
Consulting Engineer."

(Signed) DAN C. KINGMAN.

I hereby certify that Dan C. Kingman, Chief of Engineers, U. S. Army, who signed the foregoing certificate, is the Chief of Engineers, U. S. Army, and that to his certification as such full faith and credit are and ought to be given.

In testimony whereof I, Lindley M. Garrison, Secretary of War, have hereunto caused the seal of the War Department to be affixed and my name to be subscribed by the Acting Assistant and Chief Clerk of the said Department, at the City of Washington, this 29th day of October, 1914.

(Signed) LINDLEY M. GARRISON,
Secretary of War.

By JOS. RANDOLPH,
(Seal) *Acting Assistant and Chief Clerk.*"

Whereas, the Sanitary District of Chicago, a municipal corporation duly organized by an Act of the General Assembly of the State of Illinois, approved May 29, 1889, in force July 1, 1889, and Acts amendatory thereof has proceeded under said Acts and the amendments thereto to construct a channel of a capacity capable of flowing 300,000 cubic feet per minute at a velocity of one and one-quarter miles per hours, and,

Whereas, the said channel connects with the West Fork of the South Branch of the Chicago River at Robey Street in the City of Chicago; and,

Whereas, under the powers conferred by the aforesaid Acts the said District prepared plans for deepening the West Fork of the Chicago River and the South Branch thereof throughout the entire length from Adams Street in the City of Chicago to Robey Street, so as to secure a depth of twenty feet, and,

Whereas, the said plans provided for widening the said river at sundry contracted points to secure the requisite volume of flow without undue acceleration of current and in those

places where widening was not possible the plans provided for the construction of by-passes or covered waterways, and in two instances for the removal of center pier bridges and the substitution of bridges of the bascule type without central supports; and,

Whereas, the general plans for this improvement were duly submitted to the Secretary of War in 1896 and by him approved in a certain communication dated July 3, 1896, said approval being subject to limitations therein set forth among which was the requirement that plans in detail for the several parts of the work should be submitted to the War Department for approval before any work should be done thereunder; and,

Whereas, in compliance with this requirement of the said approval of July 3, 1896, the Sanitary District has submitted to this Department plans for certain by-passes, cofferdams and bridge structures which have, from time to time, received the approval of the Secretary of War, as set forth in permits issued by him under the following dates: November 16, 1897; November 30, 1898; January 13, 1899, and March 10, 1899; and,

Whereas, the said District has proceeded under these several approvals and permits to perform the work shown upon the plans; and,

Whereas, the entire main channel of the said District and the work in the Chicago and Des Plaines Rivers is now rapidly approaching completion according to said plans; and

Whereas, it is necessary under the Act of Congress of September 19, 1897, that authority shall issue from the War Department under which the said Sanitary District may cause the waters of the Chicago River to flow to the west into the main channel of the said District; and,

Whereas, the widening and deepening, already accomplished, and as further projected by the Sanitary District is a betterment to navigation in the Chicago River; and,

Whereas, it has been shown by them that they have constructed such movable dams and sluice gates as will at all times secure absolute and complete control of the volume and velocity of flow through the main channel of said District and consequently through the Chicago River;

Now Therefore, by virtue of the authority vested in me by the laws of the United States I hereby authorize said Sanitary District of Chicago to open the channel constructed by it so soon as it shall have completed all of the work outlined by it in the Chicago River.

Said document has the following endorsement:

"Respectfully submitted to the Secretary of War by the Sanitary District of Chicago for a formal permit to open the channel.

The Sanitary District of Chicago, by B. A. Eckart, one of the Trustees."

Rec'd
Jul 17 1901
Office Secretary of War.

Chicago, July 15, 1901.

"To the Honorable Elihu B. Root,
Secretary of War,
Washington, D. C.

Sir:

I have the honor to request on behalf of the Sanitary District of Chicago that your order of April 9, 1901, restricting the flow of water through the Chicago River to 200,000 cubic feet of water per minute, may be so amended as to permit the Controlling Works at Lockport, the outlet of the main drainage channel, to be so regulated as to permit at that point a flow of 300,000 cubic feet of water per minute, between the hours of 4:00 P. M. and 12:00 o'clock midnight.

The Board of Trustees of the Sanitary District have rigidly observed the restrictions of your order of April 9th, 1901, but the result has been that the water in the Main Drainage Channel has become greatly polluted and very offensive both to sight and smell and is working such hardship upon the valley communities as to evoke frequent protest from various cities and municipalities along the Des Plaines and Illinois Valleys.

By such a modification of your restricting order as is herein petitioned, it would be possible for the Sanitary District to secure much better drainage of the City of Chicago and the purification of the waters of the Chicago River without any hardship or inconvenience whatever to the interests of navigation; as the opening of the controlling works to a flow of 300,000 cubic feet of water per minute would produce no appreciable effect upon the current of the Chicago River until three hours thereafter and would not produce the full effect until about eight hours after the opening of the gates. Therefore, by again diminishing the flow at midnight to the requirements of your order, or to 200,000 cubic feet of water per minute, the normal condition in the Chicago River would be restored before six A. M. on the following day and thus no hard-

ship or inconvenience occasioned to the navigation interests of the Chicago River.

I have the honor to be, very respectfully yours,

(Signed) ALEXANDER J. JONES,
President."

War Department.

Chicago, Illinois, July 15, 1901.

Sanitary District of Chicago,
Alexander J. Jones, President.

Request that the restriction of April 9, 1901, regulating the flow of water through the Chicago River to 200,000 cubic feet per minute, may be amended to permit a flow of 300,000 cubic feet per minute between the hours 4 P. M. and twelve o'clock midnight.

(Second endorsement.)

Office Chief of Engineers
U. S. Army.

July 22, 1901.

Respectfully returned to the Secretary of War.

By an instrument dated April 9, 1901, the Secretary of War directed the Sanitary District of Chicago to regulate the discharge from the Chicago River into the Drainage Canal so that the maximum flow through the Chicago River and its South Branch shall not exceed 200,000 feet per minute.

The Sanitary District now asks that this order be so amended as to permit an increase of the flow into the canal to 300,000 cubic feet per minute between 4 P. M. and 12 midnight, daily.

It is the opinion of Major Willard, expressed in the accompanying letter of the 16th inst., that the request should be

granted subject to revocation by the Secretary of War in case the increase be found dangerous to navigation.

I concur in this opinion and recommend that the order of April 9, 1901, be modified accordingly.

G. L. GILLESPIE,
Brig. Gen. Chief of Engineers,
U. S. Army.

Chief Clerk
Oct 19 1901
War Department.

Chicago, October 16, 1901.

Received
Oct 19 1901
Office
Secretary of War.

Hon. Elihu Root,
Secretary of War of the United States,
Washington, D. C.

Dear Sir:

The undersigned respectfully petition you as Secretary of War to give us permission for an increased flow in the Chicago River, over the 200,000 cubic feet a minute, now in force by your order of July 23, 1901. We, the petitioners, inasmuch as a number of very material improvements have been made in the Chicago River, such as removing center pier bridges,

widening the river at many points, and also deepening the same, thereby allowing a much greater flow without any perceptible increase in velocity of the current, believe that we are full justified in petitioning you to grant to the Board of Trustees of the Sanitary District of Chicago permission to increase the flow from 200,000 to 250,000 cubic feet per minute, during that period of the day allowing a flow of 200,000 cubic feet per minute.

Below we enumerate the following improvements:

The old Randolph Street center pier bridge is now removed, and all obstructions which hindered navigation will be out of the way in but a few weeks, and a bascule type, with a 140-foot opening, will be erected, similar to that on Taylor Street.

The old Harrison Street center pier bridge is removed, and a new bascule type bridge with 140-foot opening, with by-passes on each side, is being erected instead.

At Taylor Street the new bascule bridge is in operation, which has a clear opening of 120 feet.

The new bascule bridge of the Chicago Terminal Transfer Railway Company is about ready to be operated, and the old center pier bridge will immediately be removed.

Just north of 12th Street the river has been widened, by the cutting away of the 12-foot corner, which projected into the river at this place.

From 12th Street to Stewart Avenue, the river has been deepened below the hydraulic grade line to a depth of 26 feet. Also a strip from 400 feet above 18th Street to Stewart Avenue was made 200 feet wide.

At Canal Street, the old jack-knife bridge with projecting piers has been removed, and a new bridge of the bascule type—the same as at State, Randolph and Harrison Streets—is in process of erection. The river from Canal Street to 22nd Street has been widened in the east side about 30 feet.

The deepening of the river to 26 feet, from 22nd Street to about 500 feet west of Main Street, is almost completed. Along this stretch the river has been widened for a distance of about 300 feet at Collision Bend.

From 150 feet east of Halsted Street to 150 feet west of Halsted Street, the river was deepened to 28 feet.

From 900 feet east of Main Street to 300 feet west of Main Street, the river has been widened to 200 feet.

The old center pier bridge and pier at Main Street have been removed and a new bridge of the same type as at Taylor Street is being erected.

The old center pier bridge and center pier at Ashland Avenue have been removed, and a new bridge of the Page Bascule Type, with a clear opening of approximately 140 feet, with a 40-foot by-pass on each side of the river, is in process of erection.

The removal of the State Street center pier bridge has been contracted for, and a bridge of bascule type with 140-foot clear opening, and by-passes on each side, is to be erected immediately.

In view of the foregoing improvements that are being carried out now, and many others which will follow as quickly as said work can be performed, we feel justified in asking you to permit the Sanitary District of Chicago to increase the flow as hereinbefore suggested.

The Sanitary District of Chicago has ample funds to pay for all of these improvements as fast as they are carried out and many others that are being matured, as the Legislature during last spring empowered the District to issue $5,000,000 additional bonds, besides, the tax levy will be somewhat larger than in the past.

While we believe that the improvements that have been made on the Chicago River, and the additional improvements that will be completed in the very near future, warrant us fully to ask for your permission for a full flow of 300,000 cubic feet per minute, but inasmuch as we desire to give the greatest consideration to the navigation interests on the Chicago River, we will ask only for 250,000 cubic feet per minute until the close of navigation.

Trusting that you will immediately grant us said permission, we are,

Respectfully,

Fourth Indorsement.
Office Chief of Engineers
U. S. Army.
November 9, 1901.

Respectfully returned to the Secretary of War.

By direction of the Secretary of War, the Sanitary District of Chicago is required to regulate the discharge of water into the Chicago Drainage Canal so that the maximum flow through the Chicago River shall not exceed 200,000 cubic feet per minute from midnight to 4 P. M. nor 300,000 cubic feet per minute from 4 P. M. to midnight.

Application is now made by the Board of Trustees for permission to increase the flow between midnight and 4 P. M. daily, to 250,000 cubic feet per minute.

In the accompanying report of the 5th instant, the local engineer officer Lieut. Col. O. H. Ernst, Corps of Engineers, recommends that, in lieu of the present authorized rates of flow as stated above, authority be granted the applicant to regulate the discharge so that the maximum flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day the Board to be responsible for all damages resulting thereby to navigation interests.

I concur in this recommendation; it being understood that this permission will be subject to modification should the change authorized prove dangerous to navigation.

Previous papers herewith.

Maj. J. H. Willard,
United States Government Engineer,
1637 Indiana Avenue, City.

Dear Sir:

I have been directed by the Board of Trustees of the Sanitary District of Chicago to forward to you the inclosed letter, addressed to the Secretary of War, which is in regard to increasing the flow of water in the Chicago River.

The Trustees would feel very grateful to you for your cooperation and assistance in bringing about the desired permission from the Secretary of War, and they desire that I

suggest that you take such action in the matter as you may deem consistent.

Yours very respectfully,
(Signed) WM. H. BAKER,
Vice-President.

Letterhead of the Sanitary District
of Chicago.

Chicago, Oct. 24, 1901.

Hon. Elihu Root,
Secretary of War of the United States,
Washington, D. C.

Dear Sir:

The undersigned respectfully petition you as Secretary of War to give us permission for an increased flow in the Chicago River, over the 200,000 cubic feet a minute now in force by your order of July 23, 1901. We, the petitioners, inasmuch as a number of very material improvements have been made in the Chicago River, such as removing center pier bridges, widening the river at many points, and also deepening the same, thereby allowing a much greater flow without any perceptible increase in velocity of the current, believe that we are fully justified in petitioning you to grant

to the Board of Trustees of the Sanitary District of Chicago permission to increase the flow from 200,000 to 250,000 cubic feet per minute, during that period of the day allowing a flow of 200,000 cubic feet per minute.

Below we enumerate the following improvements.

The old Randolph street center pier bridge is now removed, and all obstructions which hindered navigation will be out of the way in but a few weeks, and a bascule type with 140 foot opening, will be erected, similar to that on Taylor street.

The old Harrison street center pier bridge is removed, and a new bascule type bridge, with 140 foot opening, with by-passes on each side, is being erected instead.

At Taylor street the new bascule bridge is in operation, which has a clear opening of 120 feet.

The new bascule bridge of the Chicago Terminal Transfer Railway Company is about ready to be operated, and the old center pier bridge will immediately be removed. (Tested October 25. Opened in 1m 55s.)

Just north of 12th street the river has been widened by the cutting away of the 12 foot corner, which projected into the river at this place.

From 12th street to Stewart avenue, the river has been deepened below the hydraulic grade line to a depth of 26 feet. Also a strip from 400 feet above 18th street to Stewart avenue was made 200 feet wide.

At Canal street the old jack-knife bridge with projecting piers has been removed, and a new bridge of the bascule type—the same as at State, Randolph and Harrison streets—is in process of erection.

The river from Canal street to 22nd street has been widened in the east side about 30 feet.

The deepening of the river to 26 feet, from 22nd street to about 500 feet west of Main street, is almost completed. Along this stretch the river has been widened for a distance of about 300 feet at Collision Bend.

From 150 feet east of Halsted street to 150 feet west of Halsted street, the river was deepened to 28 feet.

From 900 feet east of Main street to 300 feet west of Main street, the river has been widened to 200 feet.

The old center pier bridge and pier at Main street have been removed, and a new bridge of the same type as at Taylor street is being erected.

The old center pier bridge and center pier at Ashland ave-

nue have been removed, and a new bridge of the Page bascule type, with a clear opening of approximately 140 feet, with a 40 foot by-pass on each side of the river, is in process of erection.

The removal of the State street center pier bridge has been contracted for, and a bridge of bascule type with 140 foot clear opening, and by-passes on each side, is to be erected immediately.

In view of the foregoing improvements that are being carried out now, and many others, which will follow as quickly as said work can be performed, we feel justified in asking you to permit the Sanitary District of Chicago to increase the flow as hereinbefore suggested.

The Sanitary District of Chicago has ample funds to pay for all of these improvements as fast as they are carried out, and many others that are being matured, as the legislature during last spring empowered the District to issue $5,000,000 additional bonds, besides, the tax levy will be somewhat larger than in the past.

While we believe that the improvements that have been made on the Chicago River, and the additional improvements that will be completed in the very near future, warrant us fully to ask for your permission for a full flow of 300,000 cubic feet per minute, but inasmuch as we desire to give the greatest consideration to the navigation interests on the Chicago River, we will ask only for 250,000 cubic feet per minute until the close of navigation.

Trusting that you will immediately grant us said permission, we are,

Respectfully,
(Signed) WM. H. BAKER,

Board of Trustees of the
Sanitary District of Chicago.

They petition for permission to increase the flow in Chicago River from 200,000 to 250,000 cu. ft. per minute, inasmuch as a number of material improvements have been made in the river such as the moving center pier bridges, widening the river and deepening it. They enumerate the improvements made in the river and those now in progress.

They believe these improvements warrant them in asking for permission for 300,000 ft. per min. but they ask for only 250,000 until the close of navigation."

Letterhead of
The Sanitary District of Chicago.

To the Honorable Elihu B. Root,
Secretary of War,
Washington, D. C.

Dear Sir:

This being the closed season of navigation and no vessel interest being jeopardized by an increased current in the Chicago River, we feel it to be in line with the duty we owe to the citizens of Chicago and the obligation which rests upon us to use every endeavor to comply with the State law which brought the Sanitary District into existence, to request you to grant us permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute. We ask this in the interest of the health of the people of Chicago. The work of this District for construction, right of way, administration and interest has already cost our citizens $41,000,000.00; and other millions are being expended in the work of deepening and widening the Chicago River and substituting bascule bridges for the obstructive center pier structures which are so harmful to navigation. Our wish is, by introducing the largest possible volume of water from the lake during the closed season of navigation, to draw into the channel the

largest amount of contamination that can be reached by the current thus introduced. As you know, for long years the discharge of our sewers has been into the lake and the resulting foul sediment defiles the shore line for miles of frontage. When storms, such as we have recently been subjected to, churn up this slimy deposit it often drifts out to our water intakes making our water supply unpalatable and unhealthful. The more of this turbid water that we can draw into our channel, the better for the health of our people and the sooner shall we be able to carry off the accumulations of sewage deposit which line our shores. We are working with a steadfast purpose of making the Chicago River what it ought to be as a navigable stream and we feel a justifiable pride in what we have already accomplished in that direction.

We are now in the courts condemning lands for widening and deepening the river which will cost this District enormous sums of money, which we will gladly pay to hasten the results we have set out to attain.

We recognize your responsibility as the guardian of the interest of navigation but we believe that you will readily admit that even such vast interest ought and must make concessions to conserve the health of 2,000,000 of people and we shall hope for your favorable action upon our petition.

Very respectfully,

(Signed) THOMAS A. SMYTH,
JOS. C. BRADEN,
ZINA R. CARTER,
THOMAS J. WEBB,

Federal Building, City.

Sir:

Although I personally delivered the maps and plans hereinafter enumerated, to you this afternoon, yet as a matter of record I think best to put it in the form of a letter:

A form of permit prepared by the attorney of the Sanitary

District of Chicago and submitted for the signature of the Secretary of War.

A description of the project of the Sanitary District for a channel to be known as the Calumet-Sag Channel designed to reverse the flow of the Calumet River.

A brief argument setting forth the causes which make this work necessary.

A map showing the water shed of the Calumet region in Indiana and Illinois.

A map showing the location of the proposed Calumet-Sag Channel.

A map showing the proposed guard lock and controlling works at entrance to the artificial channel of the Calumet-Sag Channel.

A profile on the center line of the proposed Calumet-Sag Channel.

Thanking you for your kindness in undertaking to forward this matter to the Secretary of War, I am,

Yours very truly,

(Signed) ISHAM RANDOLPH,
Chief Engineer.

Sanitary District of Chicago,
Robert R. McCormick, Pres.

Forwards form of permit desired from War Dept. for proposed Calumet "Sag Channel."

Note: See letter of Dec. 3 from Isham Randolph C. E. in lieu of the above.

"Whereas, Heretofore, to wit, on the 8th day of May, A. D. 1899, the Secretary of War issued to the Sanitary District of Chicago a permit in words and figures as follows, to wit:

"'Whereas, by Section 10 of An Act of Congress, approved March 3, 1899, entitled "An Act Making Appropriations for the Construction, Repair and Preservation of Certain Public Works on Rivers and Harbors, and for other purposes," it is provided that it shall not be lawful to alter or modify the course, location, condition or capacity of the channel of any navigable water of the United States unless the work has been

recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same; and

"'Whereas, The Sanitary District of Chicago, a municipal corporation organized under the laws of the State of Illinois, has constructed an artificial channel from Robey Street, Chicago, to Lockport, and has been heretofore granted permission by the Secretary of War to make certain improvements in the Chicago River for the purpose of correcting and regulating the cross section of the river so as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of 1 1/4 miles an hour, it being intended to connect the said artificial channel with the West Fork of the South Branch of the Chicago River at Robey Street, in the said City of Chicago; and

"'Whereas, the said Sanitary District of Chicago has now applied to the Secretary of War for permission to divert the waters of the said Chicago River and cause them to flow into the said artificial channel at Robey Street as aforesaid; and

"'Whereas, the said Sanitary District of Chicago represents that such movable dams and sluice gates as are necessary to, at all times, secure absolute and complete control of the volume and velocity of flow through the Chicago River have been constructed:

"'Now, Therefore, The Chief of Engineers having consented thereto, this is to certify that the Secretary of War hereby gives permission to the said Sanitary District of Chicago to open the channel constructed and cause the waters of Chicago River to flow into the same subject to the following conditions:

"'1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

"'2. That if, at any time, it become apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such an extent as may be demanded by navigation and property interests along said Chicago River and its South Branch.

"'3. That the Sanitary District of Chicago must assume

all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago River.

"'Witness my hand this 8th day of May, 1899.

"'R. A. ALGER,
"'*Secretary of War.*

"'JOHN M. NELSON,
"'*Brig. Gen'l, Chf. of Engrs.*
"'*U. S. A.*'"

And Whereas, The said Sanitary District of Chicago, in accordance with said permit, issued as aforesaid, did open its said channel in the said permit mentioned and caused the waters of the Chicago River to flow therein and therethrough to and into the Des Plaines River and has ever since maintained said flow of water from the said Chicago River and through its said Main Channel as aforesaid for the purposes of sanitation and commerce; and

Whereas, in furtherance of the objects and purposes of said Sanitary District of Chicago, said District now proposes to construct a channel, collateral to its Main Channel in said permit aforesaid mentioned, in order to provide a proper outlet for the drainage and sewage of that portion of said District adjacent to the Calumet River, which said proposed channel is to connect with the Little Calumet River at a point near the City of Blue Island and extend thence southwesterly along the depression generally known as "The Sag" for a distance of about sixteen miles, connecting with the Main Channel of the said Sanitary District at a point on said channel known as "Sag Bridge," or more particularly, with original Section 5, of the Main Drainage Channel. The route of said proposed channel, and its connection with said Main Channel of said Sanitary District and said Little Calumet River, being more fully and completely shown by the maps and plats hereto attached and marked Exhibits "A," "B," and "C," respectively; and

Whereas, The said Sanitary District of Chicago, pursuant to the authority vested in it by the State of Illinois, has duly ordained that said proposed collateral channel be constructed of the following dimensions, to wit: Of a width of ninety feet through the rock portions of said channel, with vertical sides, and of a width of seventy feet through the earth channel, with side slopes of five on three. The minimum depth of

said artificial channel, below flow line, to be twenty-two feet; and that, upon its completion, it be a navigable channel or canal subject to the uses of navigation to the same extent as the Illinois and Michigan Canal; and that it be so connected with the Little Calumet River as to cause the waters of said Little Calumet River to flow therein, thus reversing the said flow, at ordinary stages, from Lake Michigan, and from thence into the Main Channel of the said Sanitary District, and through said Main Channel in the same manner as the waters of the Chicago River now flow there through; and

Whereas, It further appears by the plans submitted by said Sanitary District of Chicago, and accompanying this permit, that the proper provision has been made for controlling the waters flowing from the said Little Calumet River into said collateral channel of said Sanitary District, and for the protection of the people living in the valleys of the Des Plaines and Illinois Rivers from danger to their lives or property by reason of flood waters in said Little Calumet River; and

Whereas, It further appears that the said Sanitary District of Chicago has laid out its right of way for the construction of said collateral channel and is ready to procure the same by condemnation or purchase; and

Whereas, It further appears that said right of way will cost several hundred thousands of dollars, and that the proposed channel will cost, approximately, twelve millions of dollars; and

Whereas, It further appears that the said Sanitary District of Chicago desires, before incurring the expense of procuring said right-of way and the construction of said collateral channel, to have the consent and permission of the Federal Government to the diversion of the waters of the Little Calumet River into its said collateral channel as aforesaid that it may be assured that its construction of said collateral channel will not have been in vain; and

Whereas, It further appears that the construction and maintenance of said channel, as contemplated, will be for the benefit of the health of the people of said District and in the interest of commerce and navigation of both the Little Calumet and Illinois Rivers;

Now, Therefore, The Chief of Engineers consenting thereto, this is to certify that the Secretary of War hereby gives permission to said Sanitary District of Chicago to construct

its said collateral channel, as herein proposed, and as shown by the plans transmitted herewith; and to connect the same with said Little Calumet River and to cause the waters of said Little Calumet River to flow therein and from thence into the Main Channel of said Sanitary District of Chicago and from thence into the Des Plaines and Illinois Rivers.

Witness My hand this _____ day of December, A. D. 1906.

_____

"The Calumet-Sag Channel.
The Project.

It is purposed to excavate a channel southwestward from the confluence of 'Stoney Creek' with the 'Little Calumet.' The point of beginning is in the S. W. ¼ of Sec. 32-37-14.

The line of the channel to be excavated passes through the Town of Blue Island crossing Western avenue between Canal street and Devonshire street. It passes the uplift known as 'Lane's Island,' on the south side, and enters the Sag Valley proper on Sec. 22-37-12. Thereafter following the general location of the abandoned channel formerly used as a feeder to the Illinois and Michigan Canal and commonly known as the 'Sag Feeder.' It crosses the channel of the Illinois and Michigan Canal in Section 14-37-11, near the station on the Chicago & Alton R. R. now called 'Lambert' but formerly known as 'Sag Bridge.' It enters the main channel of the

Sanitary and Ship Canal at or about Station 975 in Contract Section 5, Civil Section 14-37-11. The dimensions of this channel will be, in the rock sections and in the sections underlaid with rock, which must be walled, ninety (90) feet wide with vertical sides, with such additional width as may be necessary to admit of cutting the sides with channeling machines. The channel in earth will have a bottom width of seventy (70) feet and side slopes of five (5) feet horizontal to three (3) feet vertical. The minimum depth of water below the hydraulic grade line is to twenty-two (22) feet. The flow of water through the channel must be under absolute control and the volume of water passing through it must not exceed four thousand (4,000) cubic feet per second. In normal seasons with mean lake stages the cross section and slope of the channel will—within a moderate variation—control the volume of flow, but to meet flood conditions absolute mechanical means must be provided to control the flow volume. The means of control which form integral parts of the project are: A guard lock at the Little Calumet end of the artificial channel which can be closed upon the manifestation of flood probabilities and then operated for navigation purposes only: A movable dam which may be of the Bear Trap type or of the Stoney Gate type, whichever a fuller study of the conditions to be met shall point to as the most desirable form of construction. Under normal conditions this movable dam will be closed barring out all flow from the Calumet River. When so closed the normal flow into the artificial waterway will be through the guard lock. When it becomes necessary to close the guard lock then water will be admitted by way of the movable dam in such volume—up to the prescribed flow of 4,000 cubic feet per second—as the conditions to be met seem to warrant. There will be a moderate deepening of the Calumet River from the Guard Lock eastward as far Riverdale where the Illinois Central R. R. crosses the said river. The channel hereinbefore described is to be spanned by movable bridges. The railroads to be crossed are the Chicago, Rock Island & Pacific R. R. main line and one transfer line; the Chicago Junction R. R., the Chicago & Grand Trunk Ry., the Wabash R. R., the Chicago & Joliet Electric R. R. and the Chicago & Alton Railway.

(Signed) ISHAM RANDOLPH,
Chief Engineer Sanitary District of Chicago."

Sanitary District of Chicago,
Isham Randolph, Chf. Engr.

Project for excavating a channel, together with necessary controlling works, from confluence of Stoney Creek and Little Calumet River to Sanitary District Drainage Canal at "Sag Bridge."

Dimensions of channel, 90' wide, 22' deep requiring flow of about 4,000 cu. ft. per second, and to be spanned by movable bridges."

Argument for Reversing the Flow of the Calumet River.

The map which accompanies this report gives the outlines or boundaries of the Calumet watershed. This watershed has a total area of 825 square miles; of this area 485 square miles belong to the State of Indiana and the remaining 340 square miles belong to the State of Illinois. The occupation of this territory for urban and industrial uses began first in Illinois but Indiana is forging to the front also. The advantages of level plains easily accessible to the cheapest of all forms of transportation, water borne carriers, and offering facilities for easy and cheap railroad construction has tempted capitalists to create great manufacturing plants, such as steel mills, car building shops, ship yards and their allied enterprises, and these have found a quick response to their invitation to the railroads centering in Chicago to come in and possess so much of the land as was needed for great freight yards where the raw materials needed by the manufacturers could be assembled for convenient delivery to the furnace, the forge and the workshop; from whence the finished product would be sent forth by these same railroads to purchasers in all parts of the land. In addition to manufacturing interests are the great grain handling conveniences which have found relief from the congested and contracted conditions along the Chicago River and have been planted along the Calumet River. All of these manifold industries give employment to multi-

tudes of men, and men must live within reasonable distances of their work and the normal man must have his mate, and thus mated they must "increase and multiply and replenish the earth," and they are doing it, and the Calumet region is growing populous. Marshes once the exclusive home of wild forms of life are now being reclaimed and streets are being raised above the flow line and houses front upon them, and the debris of manufactories and the ashes from the hearths of homes are serving to lift the general plane of the inhabited places above the level of the swamp. But people make sewage and this sewage must find a vent. That vent is now into the Calumet River and the Calumet River empties into Lake Michigan and Lake Michigan furnishes the drinking water for Chicago. The wealthy may drink "hydrox," "Waukesha" and mineral waters, but the poor, who are the overwhelming majority of the population, must drink the waters of Lake Michigan and humanity, duty, interest, every known argument demands that this water supply be purified. Investigation has shown that for Chicago the solution is to be found and found only in turning away the streams which flow into the lake and giving them a westward flow into which all the city's sewers must be turned.

It is argued that this sewage can be disposed of upon sewage farms. A sewage farm to be successful must be underlaid by a porous soil. Chicago is environed by a clay subsoil overlaid in almost all cases by a black loam of uncertain depth, hence the land disposal of sewage is not a solution of its problem available to Chicago. The verdict went forth 20 years ago condemning land disposal and a re-opening of the case can only result in an affirmation of the old verdict. The Chicago River has been reversed and is doing for the territory which it serves all that its projectors designed it to do. The necessity of caring for the sewage of the entire city brought about the annexation to the Sanitary District of nearly all of the low ground of the Calumet watershed within the State of Illinois; an area of 94.48 square miles and it matters not what the population of that territory may be today, when we know that only by vigorous prosecution of the projected reversal of the Calumet River can the work be carried to completion in time to meet the necessities of the population which—if there be no arrested development—will throng this region before the waters can be made to flow westward.

Sanitary District of Chicago.

Argument for reversing the flow of Calumet River with map "D" accompanying.

Letterhead of the Sanitary District of Chicago.

September 2nd, 1907.

To the Honorable, the Secretary of War,
Washington, D. C.

Sir:

The Board of Trustees of the Sanitary District of Chicago has laid out and established a proposed right of way, which it expects to acquire, extending from the North Branch of the Chicago River, at Lawrence avenue, Chicago, to the western boundary of Lake Michigan, in the Village of Wilmette, Illinois, through which right of way it intends to construct and maintain a channel, as an adjunct to its Main Channel (including the Chicago River), extending from Lake Michigan to Lockport, Illinois.

The entrance of the proposed channel into Lake Michigan is shown upon the accompanying plat. In order to protect the mouth of the proposed channel against filling in with sand by the storms of Lake Michigan, it is proposed to construct a pile crib, filled with rock, extending out into Lake Michigan from the shore line a distance of, approximately, one thousand feet; and thence in a northwesterly direction a distance of, approximately, eleven hundred feet. It is further proposed to deposit within the limits of said proposed crib the spoil arising in the construction of the channel from the shore of Lake Michigan to the Chicago & Northwestern Railroad Company's tracks, in the City of Evanston, a distance of some two miles.

The accompanying plat of the plan outlined above is herewith submitted and the Board of Trustees will be grateful to

you if you will examine the same and approve, in order that work may be begun at as early a date as possible.

Yours very truly,
(Signed) G. M. WISNER,
Chief Engineer.

1st Indorsement.
Office District Engineer.
Chicago Rivers & Harbors.
Chicago, Ill., September 4, 1907.

1. Respectfully forwarded to the Chief of Engineers, U. S. Army, with recommendations that the applicant be notified that no objection will be made by the War Department to the constructions described in this request and its enclosed blueprint, provided that:

(a) The pier constructions, the filling behind the same, and the excavation of the proposed channel, to be under the supervision of the Chicago U. S. Engineer Office, so far as to see that the terms of the permit are not exceeded.

(b) The total diversion of water from Lake Michigan through Chicago River in the Illinois River to be no greater than already authorized by past War Department permits.

(c) The work to be commenced before December 31, 1908, and completed within five years thereafter.

2. Reasons for these recommendations are given in the report of this same date, herewith enclosed.

(Signed) W. H. BIXBY,
Lieut. Col. Corps of Engineers.

2 inclosures, 1 (b. p.) in triplicate.

2nd Indorsement.
War Department.
Office of the Chief of Engineers.
Washington,
September 10, 1907.

1. Respectfully forwarded to the Secretary of War.

2. The Sanitary District of Chicago proposes to connect Lake Michigan with the upper end of the North Branch of the Chicago River, for the purpose of diverting a limited quantity of water from the lake into the upper river so as to flush the sewage of the northern part of Chicago; and to construct a pile crib filled with rock, and other material, along the shore of Lake Michigan, about 15 miles north of the mouth of the Chicago River, for a length of about 1100 feet, and for a distance outward into the lake about 1,000 feet, reaching to about 10 feet depth of water.

3. This project has been under consideration by Lieut. Col. Bixby, to whose statement, in first indorsement hereon and in letter of the 4th instant herewith, attention is respectfully invited. Colonel Bixby recommends that the Sanitary District be advised that the War Department will make no objection to the project, as set forth in the applicant's letter, and indicated on the accompanying drawing, provided the following conditions are complied with:

(a) That the pier constructions, the filling behind the same, and the excavation of the proposed channel, shall be done under the supervision of the district engineer officer at Chicago, so far as to see that the work authorized is not exceeded;

(b) That the total diversion of water from Lake Michigan through the Chicago River into the Illinois River shall be no greater than already authorized by past War Department permits.

(c) That the work shall be commenced before December 31, 1908, and be completed within five years thereafter.

4. In this recommendation I concur.

(Signed) A. MacKenzie,
Brig. Gen. Chief of Engineers, U. S. Army.

1. Respectfully returned to the Secretary of War.
2. Previous action is shown by 2d indorsement hereon and Department letter dated September 11, 1907, copy herewith, to Mr. Wisner.
3. Attention is invited to the accompanying letter dated July 21, 1911, from Mr. Wisner, in which he described certain deviations in the structures, as built, from the plans on which the prior action of the department was based and requests that permit be granted for the construction as built.
4. Inviting attention to 1st indorsement on said letter by the district officer, Lieut. Col. Geo. A. Zinn, Corps of Engineers, I recommend that Mr. Wisner be informed, with return of one of the maps, that the department will interpose no objection to the maintenance of the structures as built and shown on map now presented provided they do not prove obstructive to navigation or otherwise detrimental to the public interests.

December 18, 1911.

Memorandum for the Secretary of War:

In 1908, the United States, entered a friendly suit against the Sanitary District of Chicago, the primary object of which was to determine the rights of the district to divert from Lake Michigan by opening a new route from the lake via the Sag crossing from Calumet Lake to the Sanitary District Canal, an amount of water in excess of what was then b diverted (so as to secure a total of 14,000 cu. ft. per second), without first obtaining a permit from the Secretary of War in pursuance of Section 10 of the river and harbor act of March 3, 1899. At the time the action was brought the district was diverting, under permission from the War Department, 250,000 cu. ft. per minute (4,166 cu. ft. per second), all of which was diverted through the Chicago River into the drainage canal, the connection with the canal being made at Robey street in the City of Chicago. No increase in this amount has since been authorized by the Department; but by letter of June 30, 1910, the Secretary of War granted the district permission to divide the amount of water already authorized to be diverted (4,166 cu. ft. per second), in such manner as to reach the drainage canal by way of the Calumet River and a connecting channel, as well as by way of the Chicago River.

The bill of complaint in the aforesaid suit was filed in the Circuit Court of the United States for the Northern District of Illinois in March, 1908, and the answer of the defendant

was filed in June of that year. Engineer Department records show nothing further in regard to the progress of the action. It is, however, understood by informal verbal statements of various parties, that the taking of evidence on the part of the Government has been completed, and that the case is now pending. It is, therefore, assumed that the case is ready for a hearing; but so far as the record shows, no hearing has so far been had, nor has a date been set therefor. It is also informally understood that the Sanitary District of Chicago contemplates securing direct Congressional authorization for the project of reversing the flow of the Calumet River and of using the waters of Lake Michigan to the extent of probably 10,000 cu. ft. per second, and that a bill to accomplish this purpose, prepared by the Sanitary District, has been submitted by it informally to the President and been under consideration by the Attorney General.

There always has been and are now many serious objections to the diversion, from not only the point of view of navigation but also of conservation of resources and of sanitation.

The annual levels of the water surface of all the Great Lakes are at present considerably below their average of the past 51 years, and are still dropping rapidly. The present Sanitary District diversion is aiding the rapidity and extent of this undesirable drop of levels, every foot of which will add greatly to the cost of water transportation on the Great Lakes and also lessen the total quantity of freight possible through the Sault, and the St. Mary's, St. Clair, and Detroit Rivers and into lake harbors.

Owing to the few and low water falls and rapids of the Illinois River route and the many and high falls of the St. Lawrence River route, the water diverted from the lakes via Chicago and the Illinois River can be utilized for power only to 1/4 to 1/3 the extent possible by its original route via the Detroit and St. Lawrence Rivers, and will cause a potential loss of power (and corresponding loss of utility or profits) to Canada and New York State, equal to three to four times what Illinois can get from the diversion by its own route. This may mean several million dollars annual loss to Canada as well as to the United States, and is consequently a great waste of natural resources.

The question of injury to public health due to dumpage of filth into rivers is now attracting marked attention throughout the United States, and many states have passed stringent

laws on this subject, sometimes of total prohibition, and Massachusetts at least has found it practicable to stop such dumpages. A national association for prevention of pollution of streams has been incorporated and more active protests and more stringent laws may be expected in future in all states affected by such dumpages. Properly handled, the present authorized diversions at Chicago are sufficient to cover all actual sanitary necessity.

Under all the above circumstances, it seems extremely desirable that, if this injunction can be made permanent, the United States should push the case to final settlement.

(Signed) W. H. BIXBY,
Chief of Engineers, U. S. Army.

December 18, 1911.

Chief of Engineers:

Memorandum for Secretary of War in regard to injunction suit pending before Federal Court in Chicago to determine extent of diversion of water from Lake Michigan for sewerage of Chicago; temporary injunction should be made perpetual and action pushed to that end."

"War Department.
United States Engineer Office,
508 Federal Building.
Misc. 495/33. HBF-r.

Chicago, Ill., Nov. 24, 1913.

From: The District Engineer Officer.

To: The Chief of Engineers, U. S. Army, Washington, D. C.

Subject: Report on Illinois and Michigan Canal.

1. Pursuant to 2nd indorsement dated Sept. 5, 1913, on E. D. 47860/24, the following report and recommendation is submitted. The report required is chiefly as 'to whether the matter is of sufficient importance to justify the U. S. in endeavoring to compel Illinois to spend moneys for maintenance of this canal.'

2. The Illinois and Michigan Canal is a link of the waterway from Lake Michigan to the Mississippi River and extends from the Chicago River to the Illinois River at La Salle, 95.82 miles. It is available for boats of about four feet draft. It is crossed by 75 bridges, 6 of which are swing bridges, the

remainder being fixed spans of heights of from 12 to 25 feet. The present condition of the canal is described in Colonel Zinn's report of March 16, 1912.

3. The importance of this route from the U. S. point of view will be considered by referring briefly to (1) U. S. grants for canal; (2) U. S. appropriations for connecting channels, and (3) surveys, all of which depend on (4) U. S. estimate of commercial importance of the route.

4. Under its authority and responsibility to promote interstate commerce the U. S. Congress in 1822, granted under certain conditions 'the route of the canal and 90-foot strips on either side thereof.' This grant has been held by U. S. Supreme Court (Werling vs. Ingersoll, 1901, U. S. Reports, Vol. 181) to have been mutually abandoned, so far as land section in question was concerned, by the United States and State of Illinois. It has since been contended that this ruling was founded on an error as to fact, it having been discovered that the map had been filed as required by the law of 1822. Further land grants were made in 1827, 1842 and 1854. Canal was completed in 1848. History of the canal up to 1885 is found in Report of Chief of Engineers for 1887, page 2128 et seq. The total receipts by Illinois for canal lands is stated as $5,886,039.88. This amount, added to the tolls, rents, etc., collected by Illinois, as authorized by the United States, is the expenditure by the United States for this canal.

5. The United States' expenditures for connecting channels should also be considered, especially those for Illinois River amounting to about $2,000,000, and those for the Illinois and Mississippi Canal amounting to about $7,000,000. The canal was completed in 1907. It is plainly seen in the reports that this Illinois and Mississippi Canal was projected and built as a link of a waterway from Lake Michigan to the upper Mississippi River territories, the other link formed by the Illinois and Michigan Canal having been provided by Congress in the indirect manner noted, the assumption being that this canal would be maintained by Illinois in suitable condition for commerce; and because this Illinois and Michigan Canal was not properly maintained or improved after 1907, when the Illinois and Mississippi Canal was completed, the possible benefits from the latter have been practically nullified. The present project now being executed for the upper Mississippi River at a cost of $20,000,000 depends for a great share of its beneficial results on a suitable connection to Lake Michigan.

6. In addition to these money expenditures for actual construction, the interest of the United States in a waterway from Lake Michigan to the Illinois River is manifested by numerous surveys ordered by U. S. Congress. At the present time there is a special board considering the waterway from Lockport south. $1,000,000 is available for beginning U. S. share of the improvement when co-operation is assured.

7. The commercial importance of this route depends on its value (1) as a local transportation line; (2) as part of route via Hennepin Canal to upper Mississippi River, and (3) as part of a route via Illinois River to the lower Mississippi River. As to the general commercial advantages, Capt. W. L. Marshall, Corps of Engineers, reported in 1890 as follows:

'This route has invited attention as a practicable locus for a waterway between the Great Lakes and Mississippi River for many years, and its advantages have been so often reported to Congress that anything herein said would be mere repetition. It is sufficient to say that the minimum channel herein estimated upon will open a channel of commerce with a maximum annual capacity of 30,000,000 tons between the Great Lakes, with its terminus at their greatest port, and a system of navigable rivers penetrating one-half of the states and territories of the Union, with a total navigable length equal to more than half the circumference of the globe.' (Report, C. of E. 1890, p. 2452.)

It is understood that the law limits discussion of commercial importance of this route to references to records. It is not considered pertinent or necessary to discuss the fundamental question of the value of inland waterways in general.

8. While the above evidence may be considered sufficient to establish the fact that the United States has considered this route important as a portion of a waterway from the lakes to the Mississippi River, the question whether this fact leads to the procedure suggested of 'endeavoring to compel Illinois to spend moneys for maintenance of this canal,' is more complex. To determine this question it would seem necessary to arrive at some conclusion as to what is the proper project for this section of waterway, and if probable result of procedure suggested is in accord therewith. In this view brief reference will be made to the assets of the route, plans and recommendation that have been made by the Engineer Department, and the attitude of Illinois to this canal.

9. The assets of this route are the old right of way and the water powers.

10. As to the right of way, Major Riche reported on Jan. 24, 1904, on the 33 miles from Joliet to Chicago as follows:

'This right of way contains some 1,040 acres, which at $1,000 per acre would be worth $1,040,000. This valuation is based upon the cost of the right of way of the Sanitary Canal through the same territory, and is not believed to be excessive, especially in view of the ease and economy with which the line could be rendered available for railway purposes.'

On this same basis the total value will exceed 2½ million dollars. The status of this asset and others pertaining to the canal and depending on U. S. grants would seem to be an essential factor to be considered in connection with any plan of future co-operation between Illinois and the United States.

11. As to the value of water power, a special board reports:

'By modification in the project submitted by the former board that will be in harmony with its report, this board is of the opinion that 100,000 horsepower can be developed by the diversion of 10,000 cubic feet per second.

Under such circumstances it seems proper that the Federal Government should assume, in its dealings with the Sanitary District of Chicago and the State of Illinois, the principal beneficiaries, that the net horsepower developed by 10,000 cubic feet per second diverted from Lake Michigan should produce a revenue of $2,500,000 per year.

The board considers that the property owners along the canal and Illinois River are equitably entitled to the water power due to the natural flow alone of the Des Plaines and Illinois Rivers, and that any power which results from an added flow diverted from Lake Michigan belongs to the people of the United States and Canada.' (H. Doc. No. 50, 61st Cong., 1st sess., pp. 28 and 29.)

The actual amount of diversion allowed from Lake Michigan, and hence the actual value of this asset, depends on the case now pending in U. S. Court between the United States and the Sanitary District, and on future action of U. S. Congress.

12. Concerning this waterway numerous surveys and reports have been submitted to Congress. A list of these documents to 1905 is found on page 8 of report of latest survey, made in 1905 (H. Doc. No. 263, 59th Cong., 1st sess.) The plans prepared by the Engineer Department for enlarging the

old canal and for waterway from Illinois River to Lake Michigan of 7, 8 and 14 feet depth will be briefly noted.

13. In 1882 a plan was submitted for enlarging the Illinois and Michigan Canal to the dimensions adopted for the Illinois and Mississippi Canal. This estimate was $2,298,919.15, of which $1,028,412 was for channel work from Joliet to Chicago River, leaving $1,270,503.15 as the estimate made then for enlarging canal not now replaced by the drainage canal. This estimate is based on 20 cents per cubic yard for earth excavation and $1.75 for rock, and provides for locks at a cost of about $28,000 each. (Annual Report, C. E., 1883, pp. 1776-7.)

14. In 1890 surveys and estimate were made for this waterway from Illinois River to Lake Michigan. The estimate for 8 feet depth was, in round numbers, $14,000,000 from Joliet to Lake via Sag route, and about $17,000,000 via Chicago River. Estimates for total waterway were:

Via Chicago River	$26,883,153
Via Sag route	23,885,400

(Annual Report, C. E. 1890, pp. 2433-4.)

15. In 1900 a special board prepared plans for waterways of 7 and 8 feet depth. The proposed route in both of these plans is as follows:

'From Utica to Marseilles in the bed of the river; thence around the Marseilles Rapids by canal; thence in the bed of the river to near *the mouth of the Kankakee; thence through the Illinois and Michigan Canal* (18.3 miles) *to the Joliet basin;* thence by canal to the Sanitary Canal at Lockport, and thence via the Sanitary Canal and Chicago River to Lake Michigan.' The project involves 12 locks and 2 dams. (Annual Report C. E., 1901, p. 3048 et seq.)

The estimate for the 7 feet depth is:

From Utica to near Kankakee River	$2,055,187
Enlarging 18.3 miles of Illinois and Michigan Canal below Joliet	1,215,904
Total, Utica to Joliet	$3,271,091

For 8 feet depth about 10 per cent. should be added.

The 4 locks to be provided in the enlarged Illinois and Michigan Canal are each 40 by 260 feet.

The stretch from Joliet to Sanitary Canal has been provided by Illinois, which reduces the original estimate from over seven million dollars to amount above.

16. In 1905 a special board prepared plans for a 14-foot

waterway. This report suggests that its plan can be altered to provide for development of water powers. (H. Doc. No. 263, 59th Cong., 1st sess.)

In 1909 a special board by direct act of Congress reported on value of water powers and if same can help defray expenses of improvement. This board finds value as $2,500,000 per year as above noted. No plan for development of power by the United States is submitted. Its development by Illinois is favored on conditions, stated briefly: that earnings shall be applied to sanitary canal and power works till same are reimbursed, then United States shall receive percentage of earnings; also that the Sanitary Canal shall receive percentage of earnings; also that the Sanitary Canal shall be made U. S. waterway. (H. Doc. No. 50, 61st Cong., 1st sess.)

17. The special board now in existence is to pass upon plans to be submitted by Illinois. The report of this board states:

'In accordance with this agreement' (U. S. Law 1822 and 1827) 'the State constructed the Illinois and Michigan Canal from Bridgeport to La Salle, and improved the upper portion of the Illinois River by the construction of locks and dams at Henry and Copperas Creek.

'For many years this waterway was a valuable transportation route, but in recent years the State has neglected it and failed to maintain it abreast of the needs of commerce. The work now proposed by the State in connection with the canal of the Chicago Sanitary District contemplates a waterway from Lake Michigan to Utica' (near La Salle), 'which although departing from the line of the old canal, substitutes a waterway more than sufficient for any probable navigation. This will in effect fulfill the original agreement between the State and General Government for this section and incidentally develop a water power which the State considers a profitable business investment.'

The report further states that with the transfer to the United States of the locks and the control of the new waterway thus created, so far as needed by navigation, and the locks and dams at Henry and Copperas Creek on the Illinois River, the obligations of the State of Illinois to the United States with reference to the maintenance of the Illinois and Michigan Canal may be considered as adequately fulfilled, and any equities of the United States in the rights of way and other properties of this canal should be transferred by the

United States to the State of Illinois. (H. Doc. No. 1374, 61st Cong., 3d sess., p. 9.)

18. It is to be noted that the above referred to surveys were ordered directly by Congress and that the question of advisability or worthiness of the project is assumed or evaded. On this question the Chief of Engineers comments on report of 1909 above, as follows:

'An estimate will also be made of the cost of an 8-foot channel from Lake Michigan to the Mississippi River at St. Louis, which later, in connection with the present 8-foot project for that portion of the Mississippi River between St. Louis and Cairo, will provide for a least depth of 8 feet from Lake Michigan to the mouth of the Ohio River. It is expected that these additional estimates will be ready for submission to Congress before its next session. The Chief of Engineers is not prepared to state definitely for consideration by Congress that the construction of either of these channels is desirable until after accurate estimates are made.'

The existing special board states: 'Considered as a business investment, a waterway of even moderate depth from Chicago to the Gulf is still more or less experimental.' (H. Doc. No. 1347, 61st Cong., 3d sess., p. 6.)

19. From the above quotations it is seen that there is no approved project for a waterway from Lake Michigan to the Illinois River; that is (1) the advisability has not been specifically adjudged by the Engineer Department, and (2) physical plans have not been approved. Any interest the Engineer Department has in the construction of this waterway must be based on its supposed advisability which rests on the same basis as does the advisability of the Illinois and Mississippi Canal, and of the Illinois River, all three of which taken together should be improved or abandoned. The latest Act of Congress authorizing the present special board assumes such advisability and provides for approval of plans. Until such plans are approved it does not seem consistent that the Engineer Department should urge any specific costly work. The Engineer Department has specifically investigated and recommended abandonment of the major portion of the old canal, and could not in justice urge enlargement except of the 18.3 miles on Joliet end of canal, without full technical investigation leading to reversal of the previous recommendations of various boards and officers.

20. As to the question whether the canal, considered as an investment, and omitting its general benefits, has been a

burden to the state, the dissenting opinion in the Burke case in 1904 is specific on this question of fact as quoted by Major Riche, Jan. 24, 1907:

'The fact should not be lost sight of that the canal thus far has not been a burden to the state, and the evidence in this record does not show it ever will be burdensome to the state. The original cost of the canal, which was approximately $5,000,000, was paid for from the sale of lands donated to the state by the General Government for canal purposes, with the express understanding *that the canal should be forever maintained by the state.* From the time of its construction to the time of the filing of this bill the canal had earned more than $6,500,000, and there now remains in the state treasury, after paying all its expenses and after refunding to the state all monies appropriated for its use, the sum of $338,695.76.' (Burke v. Snively et al., Supreme Court of Illinois, 1904,—Illinois Reports, Vol. 208,—Phillips. Full copy enclosed with my report of the 10th inst., 33,-152/14.)

21. It seems worthy of note that the Illinois and Michigan Canal during the years of its successful operation was of benefit to the people of the State of Illinois chiefly, and aside from the returns (tolls, etc.), it is noted by the report of one board that the easily estimated direct saving in freight was over $2,000,000 for five years (Annual Report, C. E. 1887, p. 2128 et seq.). The primary intention of Congress in regard to waterways is to accommodate interstate traffic. Now, that the second canal has been provided, any further benefits that might accrue, if the Illinois and Michigan Canal is maintained in suitable condition, would be distributed to the people of more than one state, under which condition the expenditures previously made for the canal by the United States will be justifiable. It appears that of late years the annual income has not been sufficient for maintenance and the necessary betterments. It is pertinent to inquire what the state has done or failed to do to cause this falling off of commerce. Discriminating railroad rates have been allowed. The canal was not kept abreast of the needs of commerce even when its income was sufficient. A railroad treated in a similar manner would have failed.

22. The history of the proposed transfer of all or part of this canal is briefly as follows: In 1882, the legislature of Illinois passed an act ceding the canal to the United States under certain conditions. A board of engineer officers appointed to consider the proposition reported:

'The Board then presents the following reasons why the United States should not accept the cession of the Illinois and Michigan Canal under the conditions of the existing act: (1) The canal should not be enlarged upon the whole of the present line; on the contrary, it would be judicious to abandon the greater portion of it. (2) The act does not provide for the cession to the United States of that portion of the Illinois River improvement now owned by the State of Illinois, and which forms an essential part of the through line.

'3rd. The act is not sufficiently definite as to the obligations which the United States would assume in accepting the transfer of the canal.

'Although the Board is of opinion that the United States should not accept the canal under the existing conditions, it is further of opinion that the water-route of which the canal forms a part should be controlled by the General Government, and that acceptance should promptly follow a proposition to transfer it under conditions so modified as to remove the objections stated.' (Annual Report C. E., 1887, p. 2160.)

23. In 1907 a bill was introduced in U. S. Congress, H. R. 24271, 59th Cong., 2d sess., whereby the United States was to cede in *toto* all rights to right of way from Joliet to Chicago River to the State of Illinois, who was to transfer same to the Sanitary District of Chicago. This bill was reported on unfavorably by the district engineer officer because the transfer gave away valuable rights as to right of way and water power, which the United States should hold until a waterway was built to the Mississippi River.

24. The object, authority, and responsibility of the United States is to secure a suitable waterway from Lake Michigan to the Mississippi River. By direct appropriations such a waterway has been or is being provided for portions of the route. For the section of the route from the Illinois River to Lake Michigan, U. S. Congress attempted to reserve the right of way in 1822. By default of Illinois this attempt became void. In 1827 Congress provided for this section by the indirect means of land grant to Illinois. When the canal's traffic was profitable the State of Illinois used it as a money-making machine; she failed to properly improve it, and it has practically fallen into decay and consequent disuse. Such a history of the canal under state control is natural and to be expected, when we consider that commerce, and especially interstate commerce, is not a state's prime care, but that numerous other needs absorb a state's

funds and governmental concern. The state's interest in this canal has heretofore been measured by the money returns she received and a little short thereof. The proposed transfers of all liabilities to the United States, the state keeping the assets, denote this same interest. The present status of this Burke case displays this same attitude. Illinois by her constitution, as interpreted by her Supreme Court, estops herself from properly maintaining this waterway, but she keeps the assets that are perhaps worth over two million dollars, instead of ceding them back to the United States. On the other hand, Illinois has built the drainage canal. Although built primarily for local interests, which properly bore the burden of its cost, its value for navigation is great, the estimate of 1890 for an 8-foot channel from Lake Michigan to Joliet being over 14 million dollars.

25. This very natural attitude of the states is presumed to be the main reason why the United States was given the authority and responsibility concerning waterways for interstate commerce. It would seem that failure to assume this responsibility and authority has resulted in the confusion and lack of progress in this case. The simplest and only direct and apparently satisfactory policy by which this waterway can be handled is believed to be the general plan usually pursued: (1) for the United States to decide if it is advisable; (2) then prepare plans that destroy no assets and include water powers; (3) appropriate necessary money for the work; (4) condemn dam sites, etc., and complete the work; (5) and then determine the ownership of the assets. It seems clear from the above history that if a suitable waterway is ever built from Lake Michigan to the Mississippi River, the cost borne by the United States will be the total cost, lessened only by all or part of the value of the assets that pertain to the route. Inasmuch as the main assets—that is, the old right of way and the water power due to the flow permitted by the United States from Lake Michigan—are believed to belong to the United States, it is not seen what the United States can hope to gain by co-operation. Whether or not these assets are turned over to Illinois in return for total or partial construction of a waterway or are realized in some other manner is of more interest to Illinois than it is to the United States. However, as the latest act of Congress on this subject provides for continuation of co-operation, the attitude of the department must be to assist this

attempt and if possible force it to a climax of execution or failure.

26. Effect of proposed procedure is foreshadowed in prior decision in this Burke case, from which is quoted the following extract from decision of Supreme Court of Illinois—Illinois and Michigan Canal:

'The question whether the *cession of* Congress, and the acceptance thereof by the state, constitute a contract on the part of the state to forever keep and maintain the canal in such condition that the general government may use it as a public highway does not arise for determination. If such a contract arose out of the grant of the land and the acceptance thereof, the complaint that the provision of the state constitution here under consideration, if construed to deny to the legislature power to appropriate any sums whatever from the public treasury for the purpose of repairing or maintaining the canal in usable condition as a public highway would impair the obligation of that contract, cannot be urged by the appellees, who appear in the suit only in their capacity as officers, which positions they hold under and by authority of the constitution of the State of Illinois and the statutes made in pursuance thereof. The rights of these appellees are not affected by any alleged impairment of the alleged or supposed contract between the Federal Government and the State of Illinois. The only person who may complain that a law impairs the obligation of a contract is one who has an interest in the enforcement of the obligation of the contract said to be impaired. (Templeton v. Horne, 82 Ill., 491; 15 Am. & Eng. Ency. of Law, 2d Ed., 1059.) If it shall be found that the grant of the lands and the acceptance thereof constitute a contract, and a question of the enforcement of the contract shall arise, the United States and the State of Illinois, in the exercise of the sovereign power which they respectively possess, it may be confidently asserted, will adjust their respective rights and obligations amicably, honorably and justly. No obligation will be impaired or repudiated. The appellees are but servants of the state, charged temporarily with the performance of duties in and about certain public affairs of the state which the state has intrusted to them to be performed, and in that capacity they appear in this proceeding. They do not represent the United States and have no power to submit for decision the question whether contract obligations accrued by reason of the cession and acceptance of the lands, much less to insist that, notwithstanding the changed conditions which have, it seems, ren-

dered the canal wholly unnecessary, if not entirely useless, as a highway to the United States, the alleged contract can only be discharged by the specific performance thereof.'

Burke v. Snively.

Richard E. Burke v. Clarence E. Snively et al., opinion filed February 17, 1904; rehearing denied April 7, 1904.

27. It is therefore assumed that the effect of the United States appearing in this case will be to establish (1st) the contention that there is a contract between Illinois and the United States, and (2d) the nature of this contract, whether it is (a) a narrow contract requiring specific fulfillment by enlarging this canal, or (b) a broad contract to provide a suitable waterway from Lake Michigan to the Illinois River. If the ruling be that the contract is a narrow one (a), it is believed that any attempt to enforce it will be, in fact, futile. The required dimensions of the canal are nowhere specified and it would seem that these dimensions must hereafter be determined, as they have been heretofore by Illinois. If the ruling be that a broad contract exists, the obligation resting on Illinois will not be lessened, but may be met by (1) specific fulfillment—enlarging old canal—or (2) otherwise providing a waterway, and such a ruling by her Supreme Court should have the effect of causing Illinois to decide promptly how this acknowledged obligation would be met. Illinois' self-inflicted paralysis in this case is perhaps more technical than it is intentional. She has the undoubted right to maintain this canal or not, according to her judgment on costs and benefits, but in case she refuses to maintain it, its forfeiture should be considered. It seems plain to me that Illinois has already forfeited this canal, but as its possession by the United States will be of no value except appropriation be made for a waterway along all or part of it, it seems advisable to help Illinois into condition so she can decide this question one way or the other, and decide it by a body capable of carrying out her decision either (1) by appropriation for maintenance of old canal or otherwise providing a waterway, or (2) by forfeiture. The general effect of the proceeding suggested will simply be to determine that the legislature of Illinois may decide whether this canal shall be maintained. The pending test case is concerning an appropriation of $50,000 made by the Illinois legislature for this canal. The enlarging of the whole canal is not the issue. The issue is the legislature's right to enlarge the canal and the obligation to do so or forfeit it, or adopt another

plan. The enlargement of part of this old canal is part of another feasible plan. The establishment of this right and obligation is important to the United States as a factor in present negotiations for co-operation, or if co-operation fails, as a factor to be considered in connection with advisability and possibly reduced total cost of execution of this work by the United States.

28. In order to consider further the effect of procedure suggested, it is assumed that the first result will be to establish the contention that there is a contract and that the nature of the contract will be left mainly to the decision of Illinois. The question will then arise as to how she can carry out her obligations. As the physical plan of the work would seem to require the approval of the United States it would seem that approval could properly be given (a) to a project for enlarging the old canal; (b) to a project for a deep waterway now under consideration by the special board and the State of Illinois; or (c) what might be called a composite plan, which is a modification of the plan prepared in 1900 'for 7 or 8 feet depth by old canal from Joliet for 18.3 miles to below the mouth of Kankakee River; thence in river bed.' The modification suggested being that the section of waterway in river bed be adapted to the Illinois plan for developing power; that is, that the two dams below Morris be located to properly develop the power. This plan would provide for navigation and could further be modified by the earnings of the two dams being applied to the construction of the two dams above Morris and changing the navigation route from old canal to the river. This plan would seem to offer the best chances of immediate results and embraces no feature disapproved by the department. This plan is proposed because at the present time the Sanitary District is apparently attempting to build a power dam just below the state dam at Joliet. Such a dam would be of no benefit to navigation, as would a dam below Morris.

29. It appears to me pertinent to submit to the department my impression as to why this question has been submitted to the United States. I think that it is primarily a local controversy between the Illinois and Michigan Canal Commissioners and the Sanitary District and others. Apparently the difficulty of deciding who shall spend the 20 million dollars authorized by the people of Illinois is the reason which delays action of the legislature, and I do not

think it is the business of the United States to take sides in this controversy, but only to use its every effort to force some kind of a decision. The compromise, or modification of plan of 1900, suggested, may be satisfactory to all parties. The cost of this plan would be about $10,000,000. Over $1,000,000 would be spent in enlarging the 18.3 miles of old Illinois and Michigan Canal. If this plan is approved by the department and could be presented to the governor of Illinois in verbal conference with the Secretary of War, or in some other manner, he might decide to submit it to the legislature of Illinois as a means of securing immediate results and incidentally saving $10,000,000. A decision in pending suit, favorable to the U. S. contention would permit Illinois to choose this plan. At the present time she is prohibited from such choice. If this plan is chosen the $50,000 now appropriated by Illinois could be used without loss, on section of canal (near Joliet) included in plan.

30. As there is an inherent element of futility in any attempt to coerce a state and the results may be only indefinite delay, such attempt is, in my opinion, justified only when it is part of a definite plan which includes action to prevent such delay or to be followed in case of such delay. It is therefore assumed that so far as the engineer department is concerned it has determined on such a definite plan, including proper time limit for attempt and alternate action. My recommendations are based on this assumption.

In this case the time allowable would seem to be the time that under existing laws is necessary for the state legislature to be assembled and to consider this question. The alternate action might be submission of the whole question to Congress with definite conclusion as to (1) advisability and (2) physical plans; and definite recommendations either to (a) abandon this waterway and its allied connections, or (b) appropriate $10,000,000, more or less, for construction of waterway and utilization of assets, providing for immediate necessary condemnation and subsequent settlement of legal questions. Such a definite attitude of the Engineer department is justified because of the present deplorable condition. Many millions of dollars, spent on recommendations of the engineer department, are practically wasted unless this waterway is built.

31. It is recommended that, in the case now pending, the United States appear and assert that there is a contract between Illinois and the United States, and further assert

that the specific performance by maintaining the old canal is the only mode of fulfillment ever adopted by Illinois and cannot be abandoned until some other mode is fully provided for unless the whole contract is abandoned and final settlement made with the United States. It is further recommended that Illinois be informed of the opinion of the War Department as to the other plans that are considered sufficient to fulfill the obligation of Illinois. Such opinion as to deep waterway plan is printed in report of existing special board above quoted. A modified plan, based on plan of 1900, is above referred to; if this plan is approved by the department, Illinois should be so informed.

(Signed) H. B. Ferguson,
Major Corps of Engineers.

7 inclosures."

Mr. Shenehon: The government also offers in evidence hydrograph of United States Lake Survey similar to U. S. Exhibit Number 5, but extending the monthly mean elevations of the lake surfaces up to and including November, 1914.

The monthly mean elevations of the water surfaces of Lake Superior at Marquette, Lake Michigan at Milwaukee, Lake Huron at Harbor Beach, Lake Erie at Cleveland, Lake Erie at Buffalo, Lake Ontario at Oswego, for the year 1913, and a portion of the year 1914. Also monthly mean elevations of the St. Lawrence River at Ogdensburg for September and October, 1913. This is an official document of the United States Lake Survey.

Extract from the official report of Mr. W. S. Richmond, U. S. Junior Engineer of the Lake Survey, dated May 19, 1911, beginning line 8, page 51, as follows:

"As a basis of comparison of these measurements with those of former years, and of study of their internal consistency, the discharge formula derived by Assistant Engineer Thomas Russell, in 1904, corrected for more recent levels to the St. Clair Flats gage, has been used. It is

Q=197,065÷35,145 (Fort Gratiot—580.52)—20928 (St. Cl. Flts.—578.18).

All discharge measurements were corrected by the quantity, 20928 (St. Cl. Flats—575.18). From each result was subtracted the quantity, 197,065÷35,145 (Ft. Gratiot—580.52) and the resulting residuals reduced to percentages of the latter quantity.

Also extract from same report, beginning on the 6th line from the bottom of page 53, as follows:

"Plate 8 shows the measurements of 1908, 1909 and 1910, corrected by the quantity, 20,928 (St. Clair Flats—575.18), plotted with respect to Lake Huron elevation at the shore position of Ft. Gratiot gage. Each plotted point represents the mean of five measurements grouped in order of lake stage. In four or five instances, a mean of 3, 4, and 6 measurements was used instead of 5."

Plate 8 referred to in this extract is Defendant's Exhibit 23 (Vol. VII, p. 138).

Extract from Appendix 3 of the Annual Report of Lieutenant Colonel G. J. Lydecker, Corps of Engineers U. S. Army, for the fiscal year ending June 30, 1900, page 5320, as follows:

"In my last annual report (page 3854, Report Chief of Engineers for 1899) I stated that we had found indications of a marked deepening since 1867, in the channel of the St. Clair River just below its head, and it was thought that this might have caused a material change in the outflow from Lake Huron during recent years; but further careful investigation shows clearly that there has been no such change in the regimen of the river. It also shows the great danger of jumping to conclusions in matters of this kind, and suggests the propriety of avoiding an expression of opinion on any important point until all the facts in the case are positively ascertained."

Also extract from the report of Assistant Engineer E. E. Haskell, same volume, page 5323, as follows:

"In my last year's report I called attention to what seemed at that time a clear case of enlargement, by scour, of the head of the St. Clair River. A preliminary survey of this reach was made by Mr. Sabin in December, 1898. The results of this survey, when compared with the chart of the survey of 1867, showed what seemed to be a cutting out of the river bed to a depth of about 18 feet greater, for an area covering a portion of the gorged reach. Upon the strength of this evidence I made the statement that appears in my last Annual Report. Early last fall Mr. Sabin called my attention to the fact that the survey of 1859 of this reach, as charted, agreed much closer with present conditions than did the survey of 1867. It immediately occurred to me that it would be well to secure the original field notes of the surveys of 1859 and 1867, and replat them on the same scale as

the detailed survey made last fall, and then compare the three surveys. Accordingly, the old notes were obtained and the surveys of 1859 and 1867, platted anew on the scale of 1:5,000, putting on all soundings taken. Tracings of these new plats were sent to Mr. Sabin and he was requested to make a very careful comparison of these with the results of his recent work. He has accomplished this, and discusses the matter very carefully in his report. His conclusions are that the changes that have taken place are small, that between 1859 and 1867, the most restricted cross section may have enlarged about 9,000 square feet, and that the line of deepest water may have moved a little westward; that between 1867 and the present time the changes, if any, are unimportant. What seemed at the outset, therefore, as a reasonable explanation for the low stage of water in Lakes Huron and Michigan, culminating in 1895, is set at naught, and we must return to the question of rainfall and evaporation for new data for a satisfactory solution."

Extract from the Report of Assistant Engineer L. C. Sabin, beginning page 5393 (1900), omitting tables 20, 21, 22, and all plates, as follows:

"FALL FROM LAKE HURON TO LAKE ERIE.

"In considering the total fall in the channel connecting Lakes Huron and Erie we are fortunate in having a series of water levels for the two lakes extending over a period of forty-five years without interruption. We have also a series at the St. Clair Flats Canal, 1873 to date, excepting the years 1879 to 1882; a series on the Detroit River at the lighthouse depot from 1867 to 1881; and a short series on Detroit River from 1861 to 1866, published in the report of Chief of Engineers for 1868. A series on the Detroit River made by the officials of the Detroit water works from 1853 to 1898, with the exception of 1860 to 1865, when only high and low stages were recorded, is also at our disposal through the courtesy of Mr. C. W. Hubbell, civil engineer to the Board of Water Commissioners of the City of Detroit.

"(Table No. 20.)

"In presenting a summary of these water levels in table number 20, only the months that are entirely free from ice have been considered, and the result for each year is the mean of the levels for the six months, June to November, inclusive. In order to obtain a continuous record of the fall in St. Clair River alone, the level of Lake St. Clair for the several years when no record was kept at the St. Clair Flats

has been deduced from the Detroit River readings by adding 0.44 foot, which is the mean fall from the Flats to lighthouse depot for six years when records were kept at both places. The results for Lakes Huron, St. Clair and Erie are shown on Pl. XVI. (It may be well to again call attention to the fact that the fall from the flats to Detroit is in reality 0.378 foot greater than shown by this table, the precise level line of 1899, having shown that discrepancy in the levels carried to New Baltimore from Port Huron at the head of St. Clair River, and from Gibralter, at the foot of Detroit River; but as this discrepancy occurs between Windmill Point and New Baltimore, it affects only the fall in Lake St. Clair.)

"The table shows clearly that since 1888 the fall in St. Clair River has been less than in former years, and the mean results for several groups of years are shown in the following table:

Number of years	Period	Mean elevation Lake Huron	Mean elevation Lake St. Clair	Mean fall.
17	1855-1872	581.81	576.36	5.45
16	1873-1888	581.92	576.33	5.59
11	1889-1899	580.23	575.17	5.06

"This change in fall in the St. Clair River has been attributed to a supposed change in regimen through the gorge at the head of the river, and since this opinion has been given some publicity it may be well to consider the question in some detail. In December, 1898, a cursory survey of the narrowest section of the river was made in accordance with your orders, and in 1899 the conditions at the head of the river were carefully developed. The results of this survey are shown on Plate I. The individual soundings are not shown on this plate, but the area was thoroughly covered, and the conditions are better represented by the submarine contours ten feet apart. The successive cross-sections of the river will also assist in bringing out the form of the channel. The 60-foot submarine contour extends from a point opposite the lighthouse to a little below section 'Arthur,' some 3,200 feet. Within the northern half of this area there is a very narrow 70-foot area about 1,400 feet long. To the westward of this area there is a shoal with a minimum depth of about 22 feet. Between this and the American shore there is a narrow channel having 36 feet of water, the 30-foot curve running up above the lighthouse about 400 feet. Between sections 'Culvert' and 'Fish' the shoal runs out, and the two channels merge in one. These characteristics are clearly brought out by the contours and cross-sections.

"Two surveys had previously been made of this locality,

one in 1859 and one in 1867. The soundings shown on the map of the 1859 survey are apparently accurately located, and in general they agree very closely indeed with the results of our recent survey. The only changes apparent since 1859 are as follows: The 70-foot area appears to have been extended about 700 feet downstream, with a width of only 50 feet. It may also have shifted to the westward a little, and the deep channel near the west shore may have diminished in width. If these changes are real the area of cross-section at the immediate head of the river remains about the same, all lines having been shifted a little to the westward. In the vicinity of section 'Arthur' but few soundings are given on the 1859 map, but it appears that the 50-foot and the 60-foot contours may have been extended downstream about 600 feet each, the 60-foot contour having terminated in 1859 about 400 feet above section 'Arthur.' The width of this section has apparently been reduced about 50 feet since 1859 by the building of docks. Below section 'Stauber' the sounding plotted are so infrequent that no definite conclusions can be drawn, though it appears that the deep-water areas have moved to the west, toward the concave bank, and a possible deepening of five feet may have taken place over small areas.

"The survey of 1867 is by no means as satisfactory, although a large number of soundings are available. The method followed seems to have been to sound on lines between shore stations without locating any of the soundings. This renders the actual location quite indeterminate. To distribute the soundings along the lines equidistant does not make the lines consistent with one another, and is indeed a very improbable distribution, considering the existing currents. A reasonable distribtuion can be made which will agree almost perfectly with present conditions, and any distribution which can be made establishes the fact that the 60-foot curve has not been extended since that time. In the central channel east of the lighthouse two 66-foot soundings were obtained in 1867 which agree with the present depth; to the westward appears the shoal, and the deep channel with 36 feet of water nearer the shore. There are four soundings of 60 feet at about section 'Fish,' one above section 'Arthur,' and one just below this section, which is the present limit of the 60-foot curve. No 70-foot soundings were obtained in 1867, but since the 70-foot area existed in 1859. as at present, and since only one line of soundings crossed this area in

1867, at a point where it exceeds 50 feet in width, it is not strange that it was missed.

"Although the data furnished by the previous surveys are imperfect we may conclude that between 1859 and 1867, the area of cross-section of the river at the most restricted point may have increased in area about 9,000 square feet for a length of about 60 feet, the 50-foot and 60-foot contours having been extended downstream about this distance. It also appears that since 1859, the deepest channel may have moved a little to the westward or toward the concave bank. There is no evidence of any important changes in area above section 'Arthur' since 1867, and it is quite certain that the limits of the 60-foot depth have not been extended downstream since that time. Below this section the depths may have increased a few feet over narrow areas.

"As to the effect of the extension of the 60-foot curve between 1859 and 1867, if the restricted cross-section acts as a submerged weir, its effect would be quite important, but if it is considered simply as a portion of the stream the effect on the slope would be very small. The mean fall in the St. Clair River from 1861 to 1867 was about three-tenths of a foot less than the fall from 1855 to 1859, but the level of Lake Huron had also fallen, and when the Huron level was restored in 1876 and 1886, the high slope was again found.

"Since the mean annual fluctuation of the water surface of Lake Erie is greater than that of Lake Michigan-Huron, the conclusion has been drawn that in high stages the slope in the connecting channel is low and that in low stages the slope is high. While, as will be shown, this is partially true as regards the seasonal changes in stage, and can easily be explained, it is an entirely erroneous conclusion as applied to years of high and low water. On the contrary, when we consider a term of years, it is found that the relation of stage to slope is well marked, though subject to occasional variations, as in the case of the fall at the head of the river.

"The relation of the fall in the St. Clair River to the level of Lake Huron is brought out on Plate XIV, fig. 1, in which the elevation of Lake St. Clair is plotted with reference to the stage of Lake Huron, the 6-month mean values for June to November being used. (Table No. 20.)

"Since the question under consideration is whether a permanent change in the slope of the river occurred about 1888, due to changes in regimen at the rapids, we will consider

the relation of slope to stage for the two periods before and after the supposed change. We have therefore computed by the method of least squares the relation of the level of Lake St. Clair to that of Lake Huron for thirty-three years, 1855 to 1888, excepting 1860, when no levels are available. The equation expressing this relation is found to be

"Lake St. Clair=574.32+0.707 (Huron stage—579)——
(eq. 1)

expressed as relation of fall to Huron stage this becomes

"Fall in St. Clair River=4.68+0.293 (Huron stage—579)
(eq. 2)

"That is, a rise in Lake Huron of 1 foot occasions an increase in fall of about 0.29 foot. While this relation is by no means fulfilled at all times it represents, as nearly as the data will allow, the normal condition existing from 1855 to 1888. Treating the eleven years, 1889 to 1899, since this change in regimen is said to have taken place, in the same manner, we find the equation—

"Lake St. Clair=574.20+.788 (Huron—579) or —— (eq. 3)

"Fall in St. Clair River=4.80+.312 (Huron—579)—(eq. 4)

"The difference between the equations (2 and 4) is in the wrong direction to indicate an enlargement of section, but this is of no consequence, for it is too small to indicate any change in area; it is due simply to the fact that Lake Huron is not the only factor controlling this fall, and it is only by taking a long series of years that we may arrive at the normal relationship.

"Having established as far as possible by this method that there has been no change in hydraulic conditions in recent years, we may now determine the equation which most nearly expresses the relation of fall to stage for 44 years' observations, and this is found to be:

"Fall=4.67+.30 (Huron—579).

"On Plate XIV, fig. 1, the straight line represents the relation of the elevation of Lake St. Clair to Lake Huron as deduced from this equation. In Table No. 21, the elevation of Lake St. Clair is computed by this equation for each year, and the results are given in column f, the computed fall is given in column g, and the error of the computed value for each year appears in column 8. It is seen that the computed values are in error as much as 0.30 foot in three years, but for thirty-three years the error is less than 0.20 foot.

(Table 21.)

"The effect of Lake Erie on the elevation of Lake St. Clair has not thus far been considered, as in the preceding equa-

tions the fall in the St. Clair River is made to depend upon the elevation of Lake Huron alone, while Lakes Huron and Erie generally rise and fall somewhat in unison on account of the similar climatic conditions and the partial control of Erie by Huron; yet they do not always act together. From 1865 to 1866 Huron fell 0.3 foot, while Erie rose 0.15 foot, and from 1866 to 1867 the reverse occurred. At such times Lake Erie must have an independent effect on the level of Lake St. Clair, and from the results of 44 years' observations we may obtain the equation expressing the elevation of Lake St. Clair in terms of the elevation of Huron and Erie as follows:

"C=576.05+.407 (H—581.46)+.452 (E—573.09) — — (6) where C is the elevation of Lake St. Clair above mean tide and H and E are the elevations of Lake Huron and Erie, respectively. By a simple transformation we find the fall in St. Clair River

"f=4.67+.593 (H—579.0)—.452 (E—571.50)— — — (7)

"In Table No. 21, column k, the difference between the observed fall and that computed by equation (7) is given for each year, and it is seen that these residuals are in general very small. The greatest error of the computed fall is 0.28 foot in 1883. There are ten years in which the error exceeds 0.1 foot and but five years when it exceeds 0.2 foot. This equation then expresses very closely the relation which has existed between the level of Lake St. Clair and that of Lakes Huron and Erie for forty-four years, and indicates that the level of Lake St. Clair is so nearly controlled by the lakes above and below it that its local supply can have little effect on the variations in its annual mean level, though it may affect its monthly mean, as will appear later.

"On Plate XVI, the computed and observed elevations of Lake St. Clair are shown by the two curves, and the correspondence is thus brought out graphically. The full line represents observed elevations and the dash line shows the computed values. Had a pronounced change in regimen taken place at the head of the river between 1886 and 1888, such as an important scour at the rapids, the same equation would not express this relationship before and after the change, because the fall in the St. Clair River would have been less for a given discharge after the scour; yet it is seen that the computed and actual elevations of Lake St. Clair are in very close agreement from 1868 to 1882, and from 1885 to 1899.

"Neither is the present low fall in the river unprecedented, for in 1866 it was lower than in the past three years, and dur-

ing the five years, 1864 to 1868, the mean fall in the St. Clair River was but 0.1 foot greater than in the past five years, although the stage was about a foot higher. During 1847 and 1848 the level of Huron was as low as at present. According to the published record the mean fall from Huron to Erie for the four months of May and October, 1847 and 1848 (the only months for which we have the Erie record in these two years), is less than seven feet, and the result at the waterworks in Detroit for the only one of these months when we have a record is consistent with the record for Erie.

"We have thus shown, first, that the surveys furnish no evidence of a change in the regimen of the St. Clair River since 1867, though they indicate that a small permanent change may have taken place between 1859 and 1867; second, that the water levels indicate that no permanent change of importance has taken place in the conditions governing the slope in the St. Clair River; and third, that the present relative elevations of the lakes is not unprecedented, and hence that there is no reason to suppose that, as far as natural conditions are concerned, the level of Lake Huron will not return to its normal stage.

"The fact still remains, however, that the mean level of Lake Huron for the past ten years is about 1.70 feet below the mean for the preceding thirty-four years, while Lake Erie is but one foot below that mean. As to the reason for this condition, it is possible that the improvement of the channel of the Detroit River may have had a slight effect, certainly not exceeding 0.2 foot. Considering the lower lake system as a whole, there is little question that the deficiency in precipitation in the recent years is sufficient to account for the present levels, and without going into this question of precipitation and evaporation, it may be said that it is quite possible the deficiency of the former and excess of the latter for Lake Michigan-Huron as compared to Lake Erie might be sufficient to account for the lower level of Lake Huron. But since the climatic conditions on the two lakes are usually similar, to attribute this difference in level to a change in this respect will not carry much weight unless established by an analysis of the existing data.

"There is a possible explanation of the question, however, which does not involve any changes in channel depth or differences in climatic conditions between the two lakes. It makes the present low water of Lake Huron depend upon natural causes which may be removed, and if at this time the

precipitation return to the normal the lakes will return to their usual stage.

"The effect of changes in slope at the head of St. Clair River upon the discharge from Lake Huron has been mentioned above, and it has been shown that a decrease in fall of 0.01 foot in 4.4 miles between G. T. R. and dry dock may occasion a decrease in discharge of approximately 1,200 cubic-foot seconds, this value having been determined by two measurements of discharge in December, 1898, when the water was backed up by ice, one of these measurements having shown a discharge of 47,600 cubic-foot seconds below the normal when the fall was 0.39 foot below that corresponding to the stage.

"During the past winter the water levels taken at Sand Beach and mouth of Black River gave the following results:

Month	Sand Beach	Black River	Fall	Normal fall without ice effect.	Difference.
January	579.38	578.52	0.86	1.20	0.34
February	579.38	578.70	0.59	1.20	.61
March	579.42	578.76	0.66	1.20	.54

"Assuming a decrease in discharge of 1,200 cubic-foot seconds for each 0.01 foot decrease in the fall at the head of the river, we derive the effect of ice on the discharge as given in the table below, and since a change in discharge of 10,000 cubic-foot seconds is equivalent to a depth of about 0.02 foot a month over Lake Michigan-Huron, we have the resulting storage as shown, which for the three months amounts to 0.36 foot:

Month.	Fall diminished by ice.	Corresponding decrease in discharge.	Storage depth.
	Feet.	Cubic-foot seconds	Feet.
January 1900	0.34	40,800	0.082
February 1900	0.61	73,200	.146
March 1900	0.56	64,800	.130
Total, three months			.36

"That is, if we accept this reasoning, the level of Lake Michigan-Huron is, in the spring of 1900, 0.36 foot higher than it would have been if we had had no ice in the St. Clair River during the past winter.

"During the fourteen years from 1875 to 1888 there was a mean of twelve days each winter when the temperature, as recorded by the weather bureau at Port Huron, went below 14 degrees F. in December and January, while from 1889 to 1899 the mean number of days in these months when the tem-

perature went below 14 degrees was six. During the past winter there were eight days in December and January when the temperature went below 14 degrees. The formation of ice depends upon the occurrence of very low temperature lasting for several days, so that it may be estimated by the number of very cold days better than by the mean temperature. Judged by this standard then, it is reasonable to suppose that the ice effect has been much less during the past ten years than it had been during the preceding fourteen years.

"Let us consider how the formation of ice in the lower St. Clair River would affect the water levels in any given year. The discharge being greatly diminished, Lake St. Clair would tend to drain off into Lake Erie during the winter, and it would be lowered to such a point that the flow through the Detroit River would approximately equal the discharge through the St. Clair. The elevation of this point would depend upon the relative effects of ice upon the two rivers, but the effect on the St. Clair is usually much greater than on the Detroit. The total fall in the St. Clair would thus be increased, while that in the Detroit would be diminished. The difference between the diminshed supply to Lake Erie and the diminished outflow following the lower level would be shown by the greater total fall between Huron and Erie during the months of ice effect than would naturally exist without ice.

"In 1873 water-gage readings were started at St. Clair Flats Canal, and have been continued since that time, except that from 1879 to 1883 readings were omitted during part of each year. We have therefore taken out in one group the means of the months for Lakes Huron, St. Clair and Erie from 1873 to 1887, omitting 1879 to 1883, inclusive, and in another group from 1888 to 1899, inclusive. The resulting mean monthly falls are given in table No. 22, and those are shown graphically on Plate XVII.

(Table No. 22.)

"Comparing the results of the first ten years with the curves of the past twelve years, the greater effect of ice during the former period seems to be clearly shown. In the first place it is noticed that the mean annual range of Lake Huron has been increased from 0.9 foot, as in former years, to 1.03 feet, the winter months now showing a relatively lower stage. The St. Clair curve is very instructive. It shows that in the earlier period the water surface of Lake St. Clair fell rapidly

in January and February, when it was drained off into Lake Erie, while in later years the subsidence of level is but half as great. But these points are most strikingly shown by the mean annual curves of fall in the St. Clair River. The range in the mean annual curve of fall for recent years is but 3 inches, whereas the range in the mean curve in the earlier period was 8 inches. A reference to Plate XVII will show the disturbance in this slope between December and April, and the very much smaller disturbance in the past twelve years. The range in the fall of the Detroit River has not been changed, though in recent years the curve is smoother. The maximum fall is shown in December as before, but the minimum, which occurred in February, is eliminated, and only one minimum that of May, is shown in the mean curve of recent years.

"A word may be added here as to the cause of the condition already mentioned, that in the channel connecting Lakes Huron and Erie, the fall is greater in those months when the water level is receding. This is occasioned by the facts, first, that Lake Erie has a greater mean annual range in level than has Michigan-Huron, due in part at least to the effect of the supply to the former from the latter; and second, that the seasons are earlier on Erie than on Michigan-Huron. Comparing the mean annual curves of Huron and Erie it is seen that Erie reaches its maximum in June, and begins to fall while Huron is still rising. The Huron curve from July to October is almost identical with the Erie curve from June to September, that is, there is practically the same subsidence in the two lakes during the three months succeeding the maximum, but since Erie is about a month in advance, the fall in the connecting channel is increasing with a falling stage. As Erie reaches its maximum a month earlier than Huron, so is its subsidence checked a month earlier, and we have from November to April a generally decreasing fall in the connecting channel. Between March and April Huron rises slowly, but Erie, on account of its earlier season has a sharp rise in this month, causing the occurrence of the lowest fall of the year either in April or May. Thus we have a cycle of changes resulting in a low slope in the first half of the year and a high slope in the latter half due to seasonal changes, but, as has been shown, the slope in the high-water years is greater than in low-water years.

To return to the question of the effect of the ice on the relative levels of Huron and Erie, it has been shown that the wa-

ter levels give evidence of much greater disturbance of the natural slope during the winter months of the years from 1873 to 1878 and from 1884 to 1887 than during the winters of the past twelve years, and that, judged by the number of cold days in each winter, the recent years have been much less favorable for the formation of ice. The probable effect of the diminished slope at the head of the river caused by ice during the past winter has been shown to be more than four inches. While this effect may be overestimated in the foregoing table, there is no doubt that in the consideration of the effect of ice we are dealing with conditions which are very potent and that the lack of ice effect due to recent mild winters furnishes a plausible explanation of the present low water of Lake Huron as compared with Lake Erie. The conclusion seems to be clearly indicated that nature has provided a system of regulating works in the St. Clair River which she has neglected to use to their full capacity during recent years."

Extract from the Report of Assistant Engineer F. C. Shenehon on page 5332, as follows:

"The wetted perimiter of the bridge section as developed by the soundings is so broken and irregular, and the water is so perturbed and deflected by the bridge piers and by a caisson that escaped during construction and lies across a portion of span 6, that the validity of results derived from such a section may be questioned.

"A discussion of this point, however, points to an error to be expected from this source but little in excess of that of an open-river section. Let it be assumed that the eddies and boilings close to the piers make correct estimates of the flow impossible in areas extending for certain distances from them, and that the caisson lying across a portion of span 6 adds another uncertain area.

"The resulting indetermination as affecting the total volume of flow may be closely estimated as follows:

"Taking the doubtful regions as those portions of the cross-sectional area extending ten feet in spans 1, 2, 8, and 9 and 20 feet from the piers in the remaining spans; adding 300 square feet for the caisson, they are as follows:

	Square feet.		Square feet.
Span 1	90	Span 7	404
2	110	8	340
3	500	9	200
4	660		
5	900	Total	4260
6	940		

"This is about 10 per cent. of the total cross-section. With a velocity taken as half that of the mean velocity of the river the discharge in question is 5 per cent. of the total volume.

"It is not probable that the errors in estimating the flow in these 19 doubtful places will all have the same sign. In some the quantity will be taken too great and in some too small, so that the summation will balance error against error and eliminate a part of them. It will, therefore, be entirely safe to assign 10 per cent. as a maximum error in the sum of the partial discharges.

"With this liberal allowance the indetermination in the volume of flow of the full river, from this cause, is seen to be 10 per cent. of 5 per cent., which is but one-half of 1 per cent.

"In view of the small cost of gauging from a bridge as compared with open-river work the bridge section warrants the large excess of coefficient work necessary to place its results in comparison with those of a simpler section with unbroken flow.

"Regarding the final results, the checking of the volume of the discharge is more reliable because the two sections present conditions so different as to require independent methods of treatment for the determination of coefficients."

Extract from page 5343, as follows:

"The third element that enters into the substation coefficient is the direction coefficient.

"The direction of the current flow was not, as a rule, at right angles to the bridge, but at midspan the trend was 2 or 3 degrees to the eastward, and nearer the piers was deflected from them, so that for each opening the threads tended to converge in a vena contracta.

"The surface indication of the direction was taken as the direction at all depths, and the angle taken by a 20-foot line flush with the water surface, to which was attached a weighted float, while the upstream end was attached to the weight of the B meter lowered from the south side of the bridge just below the water, was accepted as a basis for direction coefficient.

"This was observed for all substations, and additional observations were put in around the piers.

"The influence of the direction element on the measured discharge is minute, almost negligible.

Extract page 5353, as follows:

"In investigating the form of the vertical curves, those of stations 1 and 17 were set aside as in too shallow water for developing the curve, and the remaining 15 were divided into three sets of five each of as near the same depths as possible.

"By dividing the discharge observations with all the high gages in one group and all the low-gage measurements in the other, and taking for each group the mean of the eight-tenths depth ratios, a percentage was derived for each mean stage, high and low. A similar treatment of the velocity ratios at the subsurface depth, 565, gave likewise two ratios.

"Taken in connection with the index, through which both curves must pass at ratio 1.00, the high-gage curve was defined by three points and the low by three points. The difference in the areas of the two curves divided by the depth indicated the extent of the variation of the coefficient.

"This matter will be taken up again later in a discussion of vertical curves in the light of the added high-water observations of 1900, and it may be stated now that the eight-tenths depth ratio showed little change for change of gage, the mean change in 15 curves for a gage movement of 1 foot being but a tenth of one per cent. At 565 the change amounted to an increase of 1.2 per cent. as the mean of the 15 station curves.

"The following summary shows the distribution of the ratio change:

Series number.	Number of observations.	Mean depth.	Stations in series.	Increment in ratio for feet rise in section gauge. Per cent.	Add to coefficient on this account for feet rise in gauge. Per cent.
1.....	95	34	4, 5, 6, 7, 8	2.14	0.4
2.....	91	28	3, 9, 10, 11, 12	1.36	.3
3.....	83	17	2, 13, 14, 15, 16	.06	.0
Total.....	269	..	15	...	..
Mean.....	....	26.3	....	1.2	.2

"A second increment to the coefficient for rise of gage is due to the excess of the top feet percentage over the mean.

"Had the index been located at a percentage of depth instead of at an invariable elevation, the error of constant coefficient for the mean velocity percentage of each series would have been as follows:

"Indicated Error of Assumption of Constant Velocity.

"Coefficient When Index Is Taken at Percentage Depth.—

For 1-foot rise of gage: Series 1, constant coefficient would be 0.3 per cent. too small; Series 2, constant coefficient would be 0.3 per cent. too small; Series 3, constant coefficient would be 0.0 per cent. too small.

"Mean of 15 curves gives coefficient 0.2 per cent. too small, which is almost a negligible quantity. And so far as these observations go they tend to prove the proposition of fixed velocity relations at tenths of depth.

"An indication is given that a strong downstream wind speeds the upper strata more than those near the mid-depth, causing a slight reverse flexure to the vertical curve as it nears the surface. Two to three per cent. marks the extent of this departure from the curve of calm weather."

Extract from Appendix EEE, of Annual Report of the Chief of Engineers U. S. A. for the fiscal year ending June 30, 1901, report of Principal Assistant Engineer E. E. Haskell, page 3771, as follows:

"Our winter's work in the measurement of the discharge of this river will be of exceptional value. It has thus far been a matter of conjecture as to what effect the freezing over of the river had on the volume of outflow from Lake Huron. Assistant Sabin, in his annual report, called attention to this matter, and pointed out that, while dependent upon the weather, it might be large enough to materially affect the relative stage of water in the lower lakes. We are now prepared, or will be on completion of the reduction of our observations, to throw much light upon this matter. To anticipate our results: The temperature conditions of the early winter were such that by January 20, Lake St. Clair and the St. Clair River, from its mouth to a point above Stag Island, had frozen over. The foot of Lake Huron had also frozen over and what is familiarly known as the 'Ice Bridge' had formed at Fort Gratiot. This left open water from a point just below Fort Gratiot to a point some little distance above Stag Island. The fall between our Grand Trunk gage —near the head of the river—and the one at the mouth of Black River fell off about two-thirds. The open river above mentioned enabled us to continue discharge measurements as usual. Observations were made at Section Dry Dock until such time as floating ice enough had broken off from and run under the ice bridge to block the river from near Stag Island to a point above this section. A new section, called Craig, was immediately selected above the mouth of Black River where observations were made until the ice broke up near the

last of March. Almost immediately after the closing of the river in January, as above outlined, the discharge fell off approximately 50 per cent., and did not resume normal conditions of flow until the river became clear of ice about the middle of May. During the general breaking up of the ice, immense masses of it were forced into the river by northerly winds and so choked the flow that for a time but very little water could have found its way through. For some days Lake St. Clair was but a few inches above the level of Lake Erie. This condition of restricted flow has made itself manifest in the relative elevations of Lakes Huron and Erie, and we find that for the month just closed Lake Huron was 0.55 foot higher, while Lake Erie was 0.75 foot lower than during June, 1900. Here then is the explanation for the present low stage of water in Lake Erie, which will be thoroughly substantiated when the results from the complete reduction of our observations are ready for presentation."

Extract from the Report of Assistant Engineer Francis C. Shenehon, page 3773, as follows:

"These objections prevailed and a new section just above Point Three Points was tested. This showed a maximum velocity of about 5.5 feet per second, with a midstream depth of 60 feet and a width of 1,686 feet between terminal crib locations.

"The stream approaches this section from a long, straight course. It is free from 'boilers' and eddies."

Extract from report of Principal Assistant Engineer E. E. Haskell, for 1902, being included in the Report of the Chief of Engineers, U. S. Army, for 1902 (pages 2777-8), as follows:

"January shows a loss of discharge of 13,500 cubic feet per second; February a loss of 21,650 cubic feet per second, and March a loss of 13,080 cubic feet per second. The April indication of the Oswego gage shows too great a discharge by 3,195 cubic feet per second. The mean loss of flow for these four months spread over the whole year is about 4,280 cubic feet per second. For the month of February—the month of intense cold, when the upper river is frozen over, the loss of outflow is seen to be about 10 per cent. The loss is shown to be mainly accounted for by the increased slope in the river above the Galops Rapids, Table 22a. For February the slope from Ontario to Galops is shown to be 2.78 feet as against a normal summer slope for this stage of Ontario of 2.07 feet.

"The lessened depth on the Galops weir is due to the loss

of head caused by the river being frozen over and by the iced shallows of the approach. It is extremely gratifying to find that the efficiency of the Galops weir is so little impaired by ice that one per cent. will measure its decreased flowing power, even in February.

"This analysis is extremely satisfactory and the winter flow of the St. Lawrence may be stated with great positiveness. The storage value of the ice period is stated by Mr. Shenehon to be equivalent to about 7 inches on the surface of Lake Ontario."

Extract from the report of Assistant Engineer F. C. Shenehon, for 1902, included in the report of the Chief of Engineers, U. S. Army, for 1902, as follows:

TABLE No. 22a.—SLOPE OF ST. LAWRENCE RIVER FROM OSWEGO TO GALOPS RAPIDS, AND DISCHARGE EFFECT OF ABNORMAL SLOPE IN SPRING AND WINTER MONTHS.

Month.	Water surface Oswego.	Water surface Galops.	Slope.	Normal slope.	Excess slope.	Corresponding loss of discharge.
January	245.43	242.91	2.52	2.07	+0.45	+11,592
February	245.52	242.74	2.78	2.07	.71	18,290
March	245.83	243.23	2.60	2.09	.51	13,138
April	246.39	244.13	2.26	2.12	.14	3,606
May	246.67	244.52	2.15	2.14	+ .01	+ 258
June	246.82	244.70	2.12	2.15	— .03	— 673
July	246.77	244.63	2.14	2.14	.00	000
August	246.43	244.20	2.14	2.13	+ .01	+ 258
September	246.02	243.92	2.10	2.11	.01	— 258
October	245.69	243.57	2.12	2.10	+ .02	+ 516
November	245.44	243.34	2.10	2.09	.01	258
December	245.43	243.28	2.15	2.09	+ .06	+ 1,545
Sums					+1.88	+48,530
Means					+ .157	+ 4,044

"This loss of head in the river above the Galops Rapids, giving less water on the crest of the weir and therefore a lessened discharging power, accounts for about 4,000 cubic feet per second throughout the whole year. Part of this loss of head occurs above Ogdensburg, where a portion of the winter the water is running through a tube, of which the ice forms the upper part, instead of in an open channel, with consequent increased frictional resistance and loss of cross-sectional area, and the remainder in the ice-choked shallows above the Galops.

"Returning to Table 22, in which the discharge is measured, not by the one weir at the Galops, but by the three that have been calibrated, the following losses are shown:

Month.	Loss by Table 22a.	Loss by Table 22.	Subtract.	Loss by Table 22 corrected.
January	11,592	15,800	2,300	13,500
February	18,290	23,950	2,300	21,650
March	13,138	15,380	2,300	13,080
April	3,606	5,495	2,300	3,195
December	1,545	2,437	2,300	137
Sums	48,171	63,062	11,500	51,562
Yearly means	4,014	5,205	.....	4,297

"A comparison of the losses in the first and last columns shows a loss of efficiency of the Galops weir of about 3,300 cubic feet per second for February and about 1,900 for January. The 2,300 subtracted from the values in Table 22, is the August and December indication of the amount by which this method of investigation gives a cumulative error of result.

"Taking the area of Lake Ontario as 7,240 square miles, a discharge of 6,400 cubic feet per second continuing throughout the year represents the volume of water in the top foot of its depth. It follows that the storage value of the ice retardation of flow, 4,000 cubic feet per second throughout the year, is 4,000 divided by 6,400, or 0.625 feet. An open winter, therefore, with other conditions of inflow and rainfall and evaporation remaining normal, would result in a lowering of the surface of the lake about six-tenths of a foot."

Extract from the report of Assistant Engineer Louis C. Sabin, forming part of the report of the Chief of Engineers, U. S. Army, 1902 (pages 2822-2825), as follows:

"Winter Discharge.—In my annual report of 1900 (Report Chief of Engineers, p. 5398) attention was called to the probable effect of ice upon the discharge of St. Clair River, and the very important effect of this condition upon the levels of Lakes Michigan, Huron, and Erie. In order to test the magnitude of this effect, instructions were received to continue the measurement of discharge through the winter of 1900-1901. It so happened that this winter was a favorable one for the work, as the blocking was more nearly complete and longer continued than during the preceding or following winter.

"The ice that forms on the border of Lake Huron in the early winter finds its way into the river and is finally stopped when the weather becomes cold enough to freeze over some of the more sluggish reaches of the lower river. The ice continues to come in from the lake, the blocking becoming more complete until nearly the entire river is covered. As in some places broken pieces find their way below the surface, partial dams are frequently made. Meantime an ice bridge has formed across the head of the river, which wastes away slowly from the downstream side and is renewed from above.

"It was late in December, 1900, before the effect of ice on the discharge was apparent. During January, 1901, the running ice interfered greatly with the observations, sometimes precluding the possibility of working on the river, but from January 2, to February 2, eleven discharges were measured at section 'Drydock.' Early in February the ice reached and passed this section and eventually covered the river as far up as the mouth of Black River. In anticipation of this, Section 'Craig' had been selected, and gaging stations marked by ranges, and this section was used during February and March, when 38 discharge determinations were made. About March 23, a break occurred, the river cleared to Stag Island, and later to Algonac. It blocked again early in April, and did not finally become entirely clear until May 8. From March 25 to April 26, the conditions varied greatly from day to day, and sixteen measurements were made.

"Plate II shows the changes in the fall from 'G. T. R.' to 'M. B. R.' and from 'M. B. R.' to 'D. D.' during the period December 27, 1900, to May 31, 1901, with notes concerning the ice conditions as nearly as can be stated. On January 16,

the effect of the ice is very marked, the blocking progressing rapidly for several days. About February 2, the ice has extended up the river to section 'Drydock,' and the fall between 'M. B. R.' and 'D. D.' increases to the middle of March, when the ice has reached the mouth of Black River. A temporary break partially cleared this upper reach, and from March 14 to 23, the fall from 'M. B. R.' to 'D. D.' diminished. On March 24 a general break occurred, which restored both the falls to their normal value. Still another blockade in the lower river is shown by the sudden decrease in the fall, beginning April 17, and from this time the blockade was more or less effective until the final clearing of the river on May 8th.

"During February and March, 1901, when section 'Drydock' was blocked with ice, the discharge was measured at section 'Craig.' On this section the meter stations were 100 feet apart, the first one being 50 feet from the dock at west end of section. As the water will show at the east end of the section, it was covered by ice near the east bank, the portion of the section so covered varying from day to day, but never extending west of station 12. The discharge through the partial area represented by station 12, varied from 2,000 to 3,000 cubic foot-seconds. The discharge beyond the twelfth partial area varied from nothing to 1,500 cubic foot-seconds. The velocities were measured by the usual method up to the edge of the ice on the east side, and the discharge beyond was determined by occasional observations through the ice. The discharge beyond station 12 was so small that a considerable percentage of error in its determination would have a trifling effect on the total discharge.

"On this section the observations were so made as to give a vertical curve for each station at every complete observation for discharge. When two meters were used, one was kept at the four-tenths depth point while the other meter occupied successively the odd-numbered tenths of depth, as the one-tenth, the three-tenths, the five-tenths, etc. The following day when the station was visited the one meter remained as before at the four-tenths depth point while the other meter occupied successively the even-numbered tenths of depth.

"The greater number of the discharge measurements on this section, however, were taken with three meters—one remaining at four-tenths depth, while another occupied the surface—the one, two, three, four and five-tenths depth points, successively, and the third meter occupied the bottom, the

nine, eight, seven, six, five and four-tenths depth points, successively. The length of run for each position of the meters was in general 50 seconds, but when the three meters were at four, five and six-tenths depth, respectively, a run of 200 seconds was made. The ratio of the velocity observed at any given point in the vertical to the velocity observed simultaneously at the four-tenths depth point was obtained for each observation, and when combined these gave the coefficient by which it was necessary to multiply the four-tenths depth velocity to give mean velocity for the station. This program gave a complete vertical curve for each observation of discharge, and was equivalent to a direct measurement of the mean velocity. This method was adopted because it was known that enough discharges would not be measured on this section to warrant the refinement of obtaining the vertical curves with the multiple meter set, and the practical agreement of the measurements made at the two sections under similar conditions of slope indicate that the results so obtained are at least as accurate as the effective value of the fall can be obtained.

"Law of Winter Discharge.—In Table No. 5, is given a summary of the discharge measurements taken at section 'Drydock' during the ice period. The elevations of water surface were read from the records of the self-registering gages. The record for 'G. T. R.' was taken twelve minutes early, and of 'M. B. R.' eight minutes early it being considered that this time was required for a given elevation of water surface at the gages to have its effect at the section. In each case the observed elevation is the mean of the elevations corresponding to each observation for current velocity. The quantities in column 9, give the discharge as observed, to the nearest hundred cubic-foot seconds, without any corrections.

"Platting the observed discharges in column 9, with reference to the fall from 'G. T. R.' to 'D. D.' ($=f_2$, col. 7) indicated that the discharge varied approximately as the square root of this fall; but it also appeared that the discharges measured at a high stage were greater than those measured at a low stage. It is evident that the stage is not the controlling factor in the fall under the existing conditions. There are not enough discharges to differentiate the effects of fall and stage with any great accuracy, and the effect of the stage being a comparatively small factor that value of this effect was adopted which when applied to the observed discharge would give values for the discharge at mean stage most nearly

proportional to the square root of the fall. After several trials the following empirical equation was derived for the discharge in cubic feet per second.

"$Q = 205{,}000 \sqrt{f_2} + 12{,}000$ ('G. T. R.' + 579.2) Eq. 2 where f_2 is the fall from 'G. T. R.' to 'D. D.'

"The greatest variation of 'G. T. R.' from the stage 579.2 was 1.1 feet, giving a maximum value to the correction for stage of 13,000 cubic-foot seconds.

"In column 15 of the table this effect of the stage has been applied so that the quantities in this column represent, according to this assumption, the discharge that would have been observed, with the fall that obtained, had the water stage at 'G. T. R.' been 589.2 at the time of the observation. These corrected values of discharge have been platted, and are shown on Plate 3, where the curve $205{,}000 \sqrt{f_2}$ is also drawn.

"In column 16, the discharges, computed by equation 2, for the observed conditions of stage and fall, are given. These values compared with the observed discharges, column 9, give the residuals in column 17. It is seen that eight of these residuals are greater than 6,000 cubic second feet. It is not thought, however, that the observed discharges are in error as much as these residuals indicate, but that the greatest portion of the error is in the determination of the fall between gages. In other words, it is thought that the discharge can be more accurately measured than the actual effective fall. In column 18, equation 2 is used to derive the fall corresponding to the observed values of the discharge, and the residuals are shown in column 19. It is seen that there is but one residual as great as 0.06 foot, or three-quarters of an inch, and all but eight are less than 0.04 foot, or one-half inch. Considering, for example, discharge number 124, the discharge computed from the observed fall differs by 10,200 cubic foot-seconds from the observed discharge; the fall, however, computed from the observed discharge by the same formula differs by only 0.033 foot from the actual fall.

"When the river is covered with ice above the gage at Section 'Drydock' the fall from 'G. T. R.' to 'D. D.' increases with no increase in flow, but rather with a diminished discharge, as the blocking of the river is so much more effective. At such times, therefore, the fall in a reach of the river not obstructed by ice must be used for reference. All of the determinations for discharge taken at section 'Craig' were made under these conditions, and as the range in fall from 'G. T. R.' to 'M. B. R.' during the time these discharges were

taken was too small to develop the law connecting discharge and slope, the discharge at 'Drydock' and 'Craig' have been considered together for this purpose.

"A summary of the 'Craig' discharges is given in Table No. 6. When the discharges measured at both sections were platted with reference to the fall from 'G. T. R.' to 'M. B. R.' the value of discharge appeared to vary more nearly as f_1 0.4 than as f_1 0.5. It was also seen that for a given fall the discharge at high stage was greater than at low, although there was no connection between stage and slope. In this case it was found that if each discharge was corrected to mean stage by applying the factor 10,000 cubic foot seconds per foot change in stage, the results would then more closely follow the fall between the two gages. As before, the greatest correction for stage is 11,000 cubic foot seconds, corresponding to 1.1 feet variation in stage. There is no theoretical reason for this particular value of the stage factor, neither is there any theory advanced for the use of the exponent 0.4 applied to the fall. The equation below agrees more closely with the observed results than any other found, and the use of the exponent 0.5 results in bunching the residuals, although it has been used successfully when the discharges measured at section 'Drydock' are referred to the total fall from 'G. T. R.' to 'D. D.'

"There is one point, however, to which attention should be called in this connection: The area of cross-section of the river at the point where the 'G. T. R.' gage is established is approximately 40,000 square feet, and the cross-sectional area at the location of the 'M. B. R.' gage is approximately 60,000 square feet. (See Table No. 1 and Pl. 1, Report Chief of Engineers, 1900, p. 5363.) The flow is therefore not uniform, and the difference in velocity heads for the two sections is available for overcoming the friction between them. We should then expect the discharge to vary approximately as the square root of the observed fall plus this difference in velocity heads, and this is found to be the case in a general way; but since an equation of this form would not be convenient to use in determining the discharge from an observed fall, it has not been used.

"The equation adopted to connect the discharge and fall is as follows:

$Q = 250{,}000\ f_1\ 0.4 + 10{,}000\ ('G.\ T.\ R.' - 579.2)$ Eq. 3 where Q is discharge in cubic foot seconds, and f_1 is the fall in feet from 'G. T. R.' to 'M. B. R.'

"The quantities in column 10 of Tables 5 and 6 represent, according to the assumption that the discharge is increased 10,000 cubic foot seconds for 1 foot rise in stage, what the discharge would have been with the observed fall had 'G. T. R.' been at elevation 579.2. These quantities are platted on the diagram Plate IV, where the curve 250,000 f_1 0.4 is also shown. The quantities in columns 11 are the discharges computed from the equation 3, and these, compared with the observed discharges in columns 9, give the residuals in columns 12.

"Out of 60 measurements on the two sections, 14 have residuals greater than 6,000 cubic foot seconds, but, as in the case of the 'Drydock,' discharges referred to the fall from 'G. T. R.' to 'D. D.,' comparatively small errors in the determination of the fall will account for what appear to be large errors in discharge. The fall computed from the observed discharge for each measurement is shown in columns 13, and the indicated errors in the fall are given in columns 14. Thirteen measurements out of the 60 have residuals greater than 0.02 foot, and the largest error indicate in the fall is less than five-eighths of an inch.

"In a case where the slope is governed by the stage, and the discharge is referred to the latter, suppose one foot rise in stage to be equivalent to 20,000 cubic foot seconds; then an error of 0.05 foot in gage reading is equivalent to 1,000 cubic foot seconds discharge; but suppose a foot rise to stage results in increasing the fall between two gages from 1.0 to 1.1 feet, then if the discharge is considered a linear function of the fall, an error of 0.05 foot in the reading of one gage, resulting in the same error in fall, would be equivalent to 10,000 cubic foot seconds error in discharge. The accuracy demanded in the determination of the water level when the discharge is made a function of the slope is thus apparent, and one should not consider that the water levels are absolute, while all errors are attributed to the determination of the discharge. To illustrate that the falls are really approximate, the ranges in the value of the fall during the time occupied by the discharge measurement are given in Table No. 6 for 5 of the discharges.

"Effect of Ice on Lake Huron Stage.—We may now determine the effect of the ice upon the elevation of Lake Huron during the winters for which we have observations of the local slope. For this determination the discharges that would have taken place had the river remained clear cannot be de-

termined by equation 1, involving the elevation of Lake St. Clair, for during the ice period the diminished supply to Lake St. Clair lowers its level very much and the discharge indicated by equation 1 would be too great. In order to get a quantity with which to compare the actual discharge, the equation derived in 1900, involving only the elevation of Lake Huron, has been used.

"The discharges corresponding to the mean elevations of Lake Huron are shown in column 3 of Table No. 7. The discharges, computed from the known fall at the head of the river are given in column 4; the differences in second feet for each month are shown in column 5, and the effects in feet of depth on Lake Michigan-Huron and Lake Erie are shown in the final columns. It is seen that the effect on Lake Michigan-Huron is 0.31 foot in 1900, 0.52 foot in 1901, and 0.27 foot during the past winter. These quantities will not be affected more than about 0.03 foot by the fact that the quantities in column 3 are derived from the actual lake level instead of from the somewhat lower level that would have obtained for each month after the first had there been no obstruction. The cumulative effect on Lake Erie, however, would be considerably reduced by taking into account the fact that when the lake is lowered by the diminished supply from St. Clair River the discharge of the Niagara River is decreased, partially compensating the loss from above."

Extract from the Report of Junior Engineer Murray Blanchard (1903), included in the Report of the Chief of Engineers U. S. Army for 1903 as follows (pages 2813-14):

"Discharge of Detroit River.—The discharge section at Fort Wayne was sounded at the beginning of the season with a 70-pound 'fish' weight suspended on a No. 9 galvanized wire. The heavy weight made the deflection of the sounding wire from the vertical considerably less than in the 1901 soundings. It appears that too large a deflection correction was applied to the soundings in 1901, so that a recomputation of the area for that year has been made by applying the corrections given in Table No. 1, found on page 5330, Appendix III, Report of the Chief of Engineers, United States Army, for 1900. This table, computed by Asst. Engineer F. C.

Shenehon, has been tested on soundings made in the swift current of the Niagara River with various deflections. The close agreement of the two seasons' determinations of the partial areas on Section Fort Wayne indicates that no scour has taken place, and the discrepancy in the total areas has been attributed to errors of observation. The mean of the two determinations of the area has been used in computing all of the discharges summarized in this report, which accounts for the disagreement with the volumes of discharge summarized in the last report. The two area measurements and the mean value used are given in Table No. 1.

"The meters were rated about once a month, and a rate comparison, whenever the meters were used, was made by running them side by side on the section at the same depth. The rating equations of the meters and their application are given in Table No. 2. A comparison of all the ratings made in 1901 and 1902 is shown in Tables Nos. 3 and 4.

"Stations Nos. 4, 9, 15 and 20, were selected for vertical curve observations, and about 20 curves were measured at each station. A comparison with the 1901 multiple meter curves is shown on Plates Nos. 1 to 4. The co-efficients at the 0.3, 0.5 and 0.7 depths are those used in the discharge computations. The mean of the discharges at these depths is used as one discharge, and the means of the three co-efficients for each station agree closely for the two years, except for the shallow station No. 20, where the curve is abnormal and varies. The discrepancy on this station in the two years, although amounting to 2 per cent., would not affect the partial discharge more than 60 cubic feet per second, or 0.0003 of the average total discharge. Therefore the multiple meter co-efficients have been used for both seasons.

"In the two seasons 117 discharges have been measured with a range of 1.6 feet in the Windmill Point or Lake St. Clair stage, of 2.5 feet in the Amherstburg or Lake Erie stage, and of 50,000 cubic feet per second in the discharge. Some of the observations were made when the river was rough and the wind strong, because such conditions are generally found with extreme stages and accompany a very high or low discharge. In such cases, however, there is generally a large fluctuation in the stage of Lake Erie and an uncertainty as to the effective stage of that lake.

"In Table No. 6, the results of the discharge measurements for 1901 and 1902, are given, with the corresponding gage

readings at Windmill Point, Fort Wayne Section, and Amherstburg.

"Very respectfully, your obedient servant,

MURRAY BLANCHARD,
Junior Engineer.

MAJ. W. L. FISK,
Corps of Engineers, U. S. Army."

a—From the original record of Mr. J. W. Judson, C. E., March, 1847 and 1848, for Lake Erie are approximate.

REMARKS:—High Waters: 1790, Lake Erie = 5.50 feet above 1819. The high water of 1838, referred to as a plane of reference, is the plane adopted by the Lake Survey. Low Waters: 1822, Lake Erie, 5 feet below high water of 1838; 1826, Lake Ontario in March = —1.77 feet.

"The Record.

"The record is appended, and is compiled separately for each lake and river, and exhibits all the information obtainable except in regard to the St. Lawrence and Lake Champlain. The list is as follows: Lake Superior, 2 sheets; Lake Michigan-Huron, 4 sheets; Detroit River, 1 sheet; Lake Erie, 5 sheets; Lake Ontario, 5 sheets.

"No diagram has been drawn to exhibit the graphical record, as it has been thought wise to defer this until the final digest has been made. The authority for the information is set forth in connection with the several collections of data.

Very respectfully submitted,

J. E. MALONEY."

Extract from the discussion of Defendant's witness Mr. Lyman E. Cooley in the Journal of the Western Society of Engineers for February, 1912, as follows (pages 138-9):

"In 1819 the lakes were the lowest ever known in the history of the Great Lakes—a foot lower than they have ever gone since—at a time when man had made no impression upon the watersheds of the Great Lakes and no improvement of them. In 1838 the lakes went higher than they were ever known to have gone before or since. In fact, the French records at Detroit indicate that the water has not been higher in 200 years. The entire range was about 6½ feet between those dates. We have had, apparently, changes in the base levels, such as occurred about 1889 in the levels of Lakes Michigan and Huron, by which these lakes were lowered from 6 in. to 1 ft. The cause assigned is probably correct, the changes occurring in the outlet at Port Huron, although there is room for difference of opinion in regard to that, in view of what occurred in 1819 and again in 1838."

The discussion of Mr. George M. Wisner in Journal of the Western Society of Engineers for February, 1912 (p. 126), as follows:

"We need this water, and our right to take it should not be questioned; but it is questioned, and the result will be that, if denied the desired 4,000 cu. ft. of water, the City of Chicago must within the next ten years spend at least $20,000,000 more to take care of its sewage in a less effective manner than it would if this additional flow were available, which, according to the Government's own witnesses, would lower the level of the lake possibly 2½ inches."

Discussion of Mr. Robert R. McCormick in the Journal of

the Western Society of Engineers, February, 1912 (page 144), as follows:

"The Author.—Our meeting has been successful to this extent, that we have stimulated discussion. From my own point of view, I wish there had been elements here who would have given more spice to it. Perhaps a sense of courtesy towards this meeting prevented me from putting a little acrimony into it myself. Not that I have any feelings of that kind, but what we need is noise, noise to go outside of the four walls of this building, noise which will reach into other states. I do not magnify the facts at all when I say that if all the conditions which Mr. Cooley and I both look forward to had taken place and we went to Congress with a bill, I do not believe it would receive five votes outside of the Illinois delegation. I make that as a statement of opinion—it cannot be made a statement of fact—which has come to me through meeting as many as I have of the residents of other cities on the lake and meeting their firm conviction that the present height or the present lowness of the lake is due to the Chicago Drainage Canal, and that Chicago is finding a cheap way of benefiting itself at the expense of the country. That impression, I wish to say further, has been deliberately fostered."

Extract from the paper by Mr. Clinton B. Stewart, on the Discharge Measurement of the Niagara River at Buffalo, New York, in the Journal of the Western Society of Engineers, read December, 1899. This paper is referred to in Record Volume 6, pages 3521-2. (Page 2 as follows):

"The piers have a battir on the sides of about 1:24, so that the water width of the intermediate spans may be taken as constant. They have a length of about 35 ft. with a cut water on the up-stream end, the down-stream end being rectangular in form. Eddies are produced, by the piers, to some extent, but they do not extend more than about five ft. from the pier, and in most cases the current remains practically linear and with about the same amount of fluctuations as near the middle of the span. It is thought that little error has been introduced from this source."

And again, pages 14 and 15:

"Observations for the mean direction of flow of the river. In order to determine the mean direction of flow of the river, three discharge measurements were selected in which the direction of the current for each of the meter stations had been observed, and when the direction part of the meter had worked very satisfactorily. This gave 3 sets of 21 readings each, and

at distances apart of about 80 ft. The maximum range in direction of the current in any one of the sets was about 10°. The mean of the three sets gave an azimuth of 187°.0 from the magnetic south as the mean direction of flow of the river. The variation of the mean direction at any point from the mean direction of the whole river would not exceed 2° or 3°.

"Observations for the direction of the normal to the bridge or to the line of the discharge section. In these observations the meter was placed on the ground and lined parallel with the cross ties. About 20 observations were made at each end of the bridge. The mean of 40 observations gave the azimuth of the normal to the discharge section as 185° 1'.

"From this it will be seen that the mean direction of flow of the river is 2 degrees to the right from the normal to the discharge section, and that the mean direction of flow and the discharge section are practically at right angles.

"In the case of the individual discharge measurements, no corrections were necessary to the measured velocities on account of the direction of the current. In the case of the transverse curves, the velocities at stations near the piers have been corrected by multiplying them by the cosine of the angle from the mean direction of flow of the river."

Extract from Report on Waterway from Lockport, Illinois, to the mouth of the Illinois River, being House Document No. 1374, 61st Congress 3rd Session (page 9) as follows:

"While it appears to have been assumed that the Sanitary District may be allowed to divert 10,000 second-feet so long as actually necessary for sanitary purposes, the diversion of the waters of the Great Lakes from their natural outlet for power development alone is inadmissible, under the recent treaty between the United States and Great Britain. The future diversion of water from Lake Michigan for any purpose is fraught with difficulties. Not only has Canada an interest in the maintenance of lake levels which the United States must recognize, but every foot of water flowing through the Chicago Drainage Canal lessens the flow at Niagara Falls and at the power sites along the St. Lawrence River, where, due to the fall available, the same amount of water will create about four times the power that can be generated from it on the Des Plaines and Illinois Rivers. The treaty enables riparian owners of Canada, as well as of the United States, who consider themselves injured by such diversion, to bring suit in United States Courts to protect their interests. The claim that more than 1,000 cubic feet per second is required for purposes

of navigation cannot be maintained. The treaty, however, recognizes as proper the use of water for sanitary purposes, and it is the opinion of the Board that only such water should be diverted from Lake Michigan as is indispensable for sanitation, and then only with a provision for proper compensating works in the outlets of the lakes to prevent a lowering of their levels. Water thus diverted may be used incidentally for power purposes, but care must be exercised in authorizing the diversion of water for sanitary purposes, to restrict it to the amount necessary for those purposes alone."

Plot showing analysis of position of meter 2B with 120 pound lead, appended to letter of Mr. Francis C. Shenehon, U. S. Assistant Engineer to Principal Assistant Engineer E. E. Haskell, February 13, 1899, and referred to in the testimony of Defendant's witness Mr. Gardner S. Williams.

Profile of the St. Lawrence River and canals compiled from official records. Signed by Thomas Monro M. Inst. C. E. Commissioner.

Blueprint entitled "Drift of Current Meter B in Niagara River." Gardner S. Williams, consulting engineer, Ann Arbor, Michigan, May 27, 1914, showing an analysis of meter position.

Manuscript copy of Report Board of Engineers to investigate effect of the diversion of water at Chicago, 1895, as follows:

"UNITED STATES OF AMERICA

War Department.

Washington, Dec. 1, 1914.

"I hereby certify that the attached papers being a copy of a report dated Aug. 16, 1895, by a Board of Officers constituted by S. O. No. 14, Corps of Engineers, 1895, are true copies of the original on file in the office of the Chief of Engineers, U. S. Army.

(Signed) DAN C. KINGMAN,
Chief of Engineers, U. S. Army.

"I hereby certify that Dan C. Kingman who signed the foregoing certificate is the Chief of Engineers, U. S. Army, and that to his certification as such full faith and credit are and ought to be given.

"In testimony whereof, I, Lindley M. Garrison, Secretary of War, have hereunto caused the seal of the War Department to be affixed and my name to be subscribed by the Assistant

and Chief Clerk of the said Department, at the City of Washington, this first day of December, 1914.

(Signed) LINDLEY M. GARRISON,
Secretary of War.
By JOHN C. SCOFIELD,
Assistant and Chief Clerk.

(Seal War Department.)

"Chicago, Illinois, August 16, 1895.

Brig. Gen. William P. Craighill,
Chief of Engineers, U. S. A.,
Washington, D. C.

General:

"The Board of Engineers appointed by virtue of S. O. No. 14, C. S. Corps of Engineers to consider and report upon 'the probable effect of the operation of the Chicago Drainage Canal upon the lake and harbor levels and upon the navigation of the Great Lakes and their connecting waterways' submits the following report.

"The Board met in Chicago, August 12, 1895, and on the 13th and 14th accompanied the officers of the Drainage Canal over the line under construction. Every facility and courtesy possible has been extended by the trustees and engineers of the canal for a full investigation of the subject matter. A brief description of the canal is extracted from the printed report furnished the Board by these gentlemen.

"The Main Drainage channel of the Sanitary District of Chicago is now under contract from its confluence with the South Branch of the Chicago River, at Robey Street, in the city of Chicago, to its southern terminus, in Will County, Illinois. At the southern end of the channel the controlling works will be located. Beyond these works, the construction contemplated by the District will be the work necessary for conducting the flow from the channel in conjunction with the waters of the Des Plaines River down the declivity to and through the City of Joliet, and making such changes in the Illinois and Michigan Canal as the new conditions developed will make necessary.

"The first work put under contract extended southwesterly from the Willow Springs road, and these sections were numbered consecutively Nos. 1 to 14. Average length of sections, 1 mile. Easterly from Willow Springs road, the sections are lettered from A to O, omitting J. The lettered sections are, except for a short distance near Summit, entirely in glacial drift, defined in the specifications thus: 'Glacial drift shall comprise the top soil, earth, muck, sand, gravel, clay, hard

pan, boulders, fragmentary rock displaced from its original bed, and any other material that overlies the bed rock.'

"The sections from 1 to 14 were put under contract in July, 1892; from A to F were put under contract late in 1892, and early in 1893; and G to M, inclusive, were contracted for in December, 1893. Sections N and O were put under contract May 2nd, and section 15, August 27th, 1894.

"Earth was first broken on 'Shovel Day', September 3rd, 1892, on the Rock Cut below Lemont.

"The Des Plaines valley is traversed by the river from which it takes its name—a stream of wide fluctuations with no constant and reliable fountain supply. During some seasons its whole discharge would pass through a six-inch pipe, and at others its volume reaches 800,000 cubic feet per minute. Then it rolls majestically along, flooding the whole valley. Such being the situation, control of this stream was a condition precedent to the successful prosecution of the work upon the main Channel. This control has been secured by the outlay of nearly $1,000,000 in constructing what is known as the River Diversion Channel.

"About 13 miles of new river channel had to be excavated with the location of the Main Drainage Channel, and about nineteen miles of levee built to divorce the waters of the Des Plaines watershed from the channel which is to receive the waters of Lake Michigan and pass them on to the Mississippi River, via the lower Des Plaines and the Illinois Rivers. The width of the River Diversion Channel on the bottom is 200 feet, side slopes 1½ to 1, grade generally 12-100 per 1,000 feet.

"At the head of this River Diversion it was necessary to provide a safety valve in the form of a spillway, to allow surplus water to flow towards Chicago, because arrangements have not as yet been perfected for carrying the entire flood waters of the Des Plaines through Joliet.

"This spillway is a concrete dam capped with cut stone, and its wings faced with stone masonry; it is 397 feet long and its crest is 16.25 feet above Chicago datum (this datum is referred to the low water of Lake Michigan of 1847, and is 579.61 above sea level at Sandy Hook). No water flows over this spillway until the volume passing the water gage above it reaches 300,000 cubic feet per minute.

"The cross-section of the earth sections from A to E inclusive is 202 feet on the bottom, side slopes two to one. This section extends for about 500 feet into the west end of F and then reduces to 110 feet on the bottom, preserving the

same side slopes. The explanation for this change of cross-section is as follows: Throughout the rock sections, and those sections in which there is a preponderance of hard material, or where rock may appear, the section adopted is designed according to law for a flow of 600,000 cubic feet of water per minute, which means provision for a population of 3,000,000 people. The narrow channel provides for a flow of 300,000 cubic feet per minute, or for about the present population of Chicago. The enlargement of the narrow channel can be made by the easier method of excavation, such as dredging; whenever the needs of the city require it. The grade throughout the lettered sections is one foot in 40,000 (.025 per 1,000 feet) and the bottom of the channel at Robey Street is 24.448 feet below datum. The numbered sections from No. 1 to No. 6 inclusive are underlaid with solid rock. The width of the bottom in rock, is 160 feet, and walls of masonry laid in cement will be built upon the rock surface to a height of five feet above datum. Section 7 to 14, inclusive, are in solid rock; width at bottom 160 feet, sides vertical, prism taken out in three stopes with offset of six inches on each side for each cut, making top width of 162 feet; grade in rock 1 foot in 20,000 (.05 per 1,000).

"Section No. 15 is also in rock and its cross sections is enlarged at its south end so as to form a 'windage basin' in which large vessels may be turned around. The controlling works are located on this section. These works will consist of gates or movable dams by which the flow of water from the Main Channel into the tail race, which is to deliver the outflow into the Des Plaines River, can be controlled.

"This river below Lockport follows the trough of the valley down a steep declivity to the canal basin in Joliet. The fluctuations in Lake Michigan, by varying slope of water surface, will be felt at the controlling works, and provisions must be made to meet these fluctuations within a range of five feet above datum and eight feet below, or an extreme oscillation of 13 feet. The fall from datum at the controlling works to the level of the upper basin will be about 42 feet, in a distance of about 4 1/3 miles. As the plans for controlling works have not been finally adopted by the Board of Trustees they cannot now be discussed.

"The total amount of excavation involved in the construction of the Main Channel is 26,077,765 cubic yards of glacial drifts and 12,071,668 cubic yards of solid road, or an aggregate of 38,149,433 cubic yards, to which must be added the

material excavated from the River Diversion; glacial drift, 1,564,403 cubic yards; solid rock, 258,926 cubic yards; total River Diversion, 1,823,329; grand total Main Channel and River Diversion, 39,972,762 cubic yards. All of this work is now under contract and in addition thereto 384,958 cubic yards of retaining wall."

In response to the request of the Senior Member of the Board the Board of Trustees of the Sanitary District of Chicago has furnished a report on Lake Level effects on account of the main channel of the Sanitary District of Chicago containing briefs by Trustee L. E. Cooley, C. E., and by Thos. T. Johnston, Assistant Chief Engineer, accompanied by numerous blue prints.

These papers present a full discussion of the subject as viewed by the canal officials, and will be found in the Appendix marked A.

What Is the Outflow of the Lower Lakes?

In November, 1891, the Chief of Engineers U. S. A., at the request of the Secretary of the American Society of Civil Engineers (who had been asked by the Chief Engineer of the Montreal Harbor Commission of Canada, to suggest the subject), ordered a set of observations made to determine the amount of water flowing down the Niagara River. The time was especially propitious as the water was then very low.

The results of these measurements were somewhat unexpected, and they were repeated in May, 1892. The second set corroborated the first, and the whole formed the subject of a report to the Chief of Engineers, which appeared in his annual report of 1893, page 4364, and following. But, as the subject was important, the "Engineering News" anticipated the appearance of the official report by publishing in its issue of March 8, 1893, this report, with the permission of the Chief of Engineers. This publication was the first ever made in which as a result of careful measurements a relation between the level of the lakes, and their outflow, or discharge, had been established and given to the public. Prior determination of this discharge had not attempted to detect this relation, and nothing more than a general determination of a season's work had been published.

In all plans for the Chicago Drainage Canal the early measurements had been taken, and those studying the subject chose such isolated figures as suited them best.

The report of 1892, being so late in appearance, long after

the Drainage Canal was put under construction, escaped the notice of many who are interested in navigation, for two reasons. Some were too busy to see anything, unless specially brought to their notice. Others thought the whole matter already fully canvassed, and settled. It is true there is nothing showing that the consent of Congress had been asked, for this enterprise. Certain that the subject had not been treated as an Interstate affair; to say nothing of its being an International affair. The United States has always been slow to move; with its many sleeping rights it has for many years been loath to exercise them. Not till 1888 did it begin to exercise positive legislation over its navigable waters in order to preserve them for all its citizens. Each River and Harbor bill since then is found to have sections strengthening the hands of those who wish to keep the waterways open, and in good order for all classes of navigators. Not till 1890 had any prohibitive clauses been enacted into laws forbidding, for example, the destruction of channels by improper dumpings. Saw mills went their own unchecked way every year clogging up the streams. Railroads bridged all smaller streams, in the states, without interference from the United States. Many other features can be quoted. But it is sufficient to say that all that is now changed. The adopted policy is to defend, as well as improve all water courses, now navigable, or probably navigable in the reasonably close future. Waterways are under the charge of the United States, and there is no likelihood of their being abandoned for some time to come.

With this an established fact it is impossible to think that U. S. supervision shall not be extended to the Chicago Drainage Canal in due time. Under whatever law built, and for whatever purpose constructed, just so soon as it is shown that that canal affects, or becomes a part of the system of navigable waterways of the United States some supervision or control of it must follow. When boats use it for harbor purposes; when its waters add to the Illinois River, or take from the lakes, they alter natural conditions and the matter rises for consideration under national authority.

The water levels of the Great Lakes are very delicate. Storms, barometric changes, rainfall, even tidal changes are felt. Records show at Buffalo no less than 13 feet as a total possible change, between the lowest and the highest gage readings. Each lake is a basin. The water is constantly pouring in from not only one, but several inlets. The over-

flow, however, is now always out of the one outlet provided for that purpose; the second one formerly at Chicago, has been plugged up.

As in our basins when the water rises enough to take two, three, or more of the small holes to carry it off, it is always to be noted that those holes are always carrying that surplus off. They do not wait until the water has time to pass from one end to the other. In the same channel the head alone governs the rate of outflow, and that head is measured by the gage reading at the outlet. The supply of water in the lake: The net supply, allowing for evaporation, is the sole cause of the outflow. That supply depends solely upon rainfall, but the lake when it receives more than it has been reciving must discharge more. When it has less there is less to run out. If the outlet be dug down, or new ones made the water runs off faster than it ran off before.

The outflow is instantly affected by a changed inflow; Provided there is enough such to increase or reduce the head. If we have a rainfall of one inch over the lake area (and such are not uncommon events), there is a head of one inch to run off. But if there are two outlets to run out of, instead of one this inch must run off sooner than through the one.

If the new outlet should reduce the levels of Lake Michigan and Huron about 6 inches this effect will be produced in full in about two years; it is not then a question of many years as some suppose.

We may feel very sure, therefore, that in this question two points are certain.

1st. The drainage canal is not solely a State affair; but a national one.

2nd. The tapping the lakes must affect their levels. But it is said, first, that the changes in levels does not concern shippers, and then that at most the affects will be trifling.

If one watched carefully the course pursued by shippers one would see that as a rule each vessel carries all that it can take, and get out of its port, or into that it intends to reach. Vessel owners, and managers are very shrewd, watchful men. They know what they can safely carry allowing for storms, and short detentions arising from passing causes. They average pretty well the practicable depths, and carry all the channels will stand. They are as conversant as are theorists about the effects of storms, but they keep good watch on ruling depths. Now should it be certain that these average depths were reduced three inches, or six inches, they must load ac-

cordingly. And not only the large boats, but also the small ones using the small harbors that the large ones cannot go into. All must lose the three, or six inches, as it may be; and not for one, or more trips, but for all trips, and for all time; a diminution of capacity is not a single tax, but a continuous one. A vessel that when light draws six feet, and loaded twelve feet, must lose three inches out of 72, say four per cent. in capacity each loading; a vessel drawing 12 feet light and 20 feet loaded, would lose somewhat over three per cent. in capacity at each end every loading.

Should the loss of levels be six inches instead of three, then these figures become doubled. Will the loss be six inches or will it be three? This is an important question and we have only the Niagara River discharge observations from which to answer it. These cover a range of about 1 foot and eight-tenths. There were scattering observations outside these limits, but the mass of results was secured between gage readings, mean lake level, the highest, and —1. '85. The "smooth curve" as published enables us to note the fall of 0' .53 on the gage per 10,000 cubic feet per second for the first foot of fall and 0' .44 for the whole.

These observations, especially at the lower readings are erratic and indicate a need for more measurements, especially at these levels. This lower portion of the gage should be studied and additional observations made, and the Board is a unit in suggesting the importance of a series of gagings of the St. Clair River at the present time for this purpose, and to furnish additional knowledge of the relation between gage readings, and discharge. The subject is of such general bearing upon the navigation of the lakes, that it demands careful treatment, and full data. The Niagara data do not show how much Lakes Huron and Michigan would be lowered, even if 0'53 were the net loss to Lake Erie. The opinion expressed by Mr. Johnson that the effect on the two upper lakes would be some 15 per cent. greater than upon Erie would seem to point to a probable loss of say 0'61. This possible loss of seven inches certainly is important enough to justify careful measurements of the discharge through the St. Clair. It is true that the law as it stands, and the intention of the Trustees contemplates the abstraction of only 300,000 cubic feet under present conditions, but after the canal is opened measurements would not be so instructive, and we must assume that ultimately the entire 600,000 cubic

feet per minute will be drawn from Lake Michigan as required by the State Law.

The abstraction of 10,000 cubic feet of water per second from Lake Michigan will lower the levels of all the Lakes of the system except Lake Superior and reduce the navigable capacities of all harbors and shallows throughout the system to an extent that may be determined, if at all, by actual measurements only. Under the laws of the United States these changes in capacity cannot be made without Federal authority, and to enable the executive officers of the United States to act advisedly in the matter it is necessary in the opinion of the Board not only that these measurements be taken but that the money cost of restoring the navigable depths in channels and harbors be carefully estimated.

In this connection the Board submits without expression of opinion an estimate prepared by Mr. Charles H. Keep, Secretary of the Lake Carriers Association, of the commercial losses in carrying capacity of the Lake fleet, should a reduction be made in Lake levels of one, three or six inches.

(Appendix Marked B.)

The Board notices that the same peculiarity exhibited by the Niagara discharge curve, is pointed out by Mr. Johnston as existing in the Morris, Ill., and South Branch Chicago River curves. (See page 25 Appendix A1.)

The Board also notes Mr. Johnston's conclusions on page 23, Appendix A-1, that "applying the reasoning to the St. Clair and Detroit Rivers, then the value of Q'—Q may be taken from the diagrams illustrating the tables before described, the only uncertainty being as to the value of "d." Suppose "d" to be unity, and the mean depth 20 feet. Then Q'—Q will equal something greater than 20,000 cubic feet per second," which practically corresponds with the deductions made from the Niagara River observations.

So many uncertainties arise in the application of hydraulic formulae that the only way to ascertain the approximate discharge of these streams is to measure them for periods long enough to eliminate accidental fluctuations and to cover all stages.

While the navigable capacity of all harbors and channels on the Great Lakes below St. Marys Falls will be injuriously affected by a diminution in depth, the navigability of the inner harbor of Chicago will be diminished also by the introduction of a current therein, which in the present condition of the river even with the minimum flow of 5,000 cubic feet per

second or 300,000 cubic feet per minute is entirely inadmissible. The estimates of the effect of the Drainage Canal upon this harbor should also consider this element.

The Board of Trustees have not yet determined upon a plan of treatment of this navigable channel, and their plans may be such as may improve, impair or destroy its utility as a navigable river.

All of which is respectfully submitted.

Statistical Report of Lake Commerce passing through Canals at Sault Ste. Marie Michigan and Ontario during season of 1913. This is not to be published in the record, but is placed in the hands of the Commissioner for such reference as either party to this suit may wish to make.

Extract from the letter of Colonel Charles E. L. B. Davis, Corps of Engineers U. S. Army to the Chief of Engineers dated January 12, 1906, and printed in House Document Number 266, 59th Congress, 2nd Session, as follows, pages 5-6:

"Survey of Ship Channel Connecting Waters of the Great Lakes Between Chicago, Duluth and Buffalo.

United States Engineer Office,
"Detroit, Mich., January 12, 1906.

"General: 1. In accordance with instructions contained in Department letter of May 2, 1905, I have the honor to submit the following report and estimates of cost of a—

"Ship channel connecting waters of the Great Lakes between Chicago, Duluth, and Buffalo, with a view to obtaining depths of twenty-two and twenty-five feet, respectively, and sufficient width.

"2. The present project for a ship channel through the connecting waters of the Great Lakes was adopted by the River and Harbor Act of July 13, 1892, the object being to provide a navigable depth of 20 feet by excavating channels to a minimum width of 300 feet through the shoal places in the specified waters, at an estimated cost of $3,340,000, the scope of improvement being limited to shoals not specifically provided for by the then existing appropriations—that is,

the appropriations made specifically for improving the channels in St. Marys River, St. Clair Flats Canal, and Detroit River.

"3. Under approval of the War Department, dated October 20, 1892, operations were commenced in the spring of 1893, and by 1897 channels of the prescribed depth of 20 feet and widths of 300 feet or more had been excavated through all of the shoal areas originally specified in the project. Since 1898 the work has consisted in increasing the width and depth of channels at angles, some exposed places in the open lake, and other critical points, and in removing many isolated shoals of comparatively small area that have been found to interfere with the safe navigation of the channel by the larger class of vessels now in use.

Planes of Reference.

"4. At the time of the adoption of this project certain planes of reference were adopted for the various portions of the connecting waters referred to mean tide level at New York expressed in feet above that level. For the ten years between 1892 and 1902 the prevailing water levels of Lakes Huron, St. Clair and Erie had been almost continually below the assumed elevations, and in consequence the actual draft available was considerably below the 20 feet called for by the project.

"5. For this reason Maj. W. H. Bixby, Corps of Engineers, then in charge of this District, in his project of October 13, 1902, for the improvement of Middle and West Neebish Channels, recommended certain changes in these reference planes which received the approval of the Secretary of War October 31, 1902, and which have been used in the estimates.

"6. These reference planes are as follows: 601.5 for Lake Superior, 580.2 at the head of Little Rapids, 579.3 through Hay Lake, 578.9 in Little Mud Lake, 578.8 at Sailors Encampment, in Mud Lake, and Lake Huron. Such levels correspondent to 573.8 in Lake St. Clair (head of canal) and 570.8 in Lake Erie, these being the monthly means of November, 1895, when the three lakes taken together were at their lowest since 1860, when the records of Lake Michigan and Huron were commenced."

Extract from the Report of Principal Assistant Engineer Francis C. Shenehon on the hydraulic investigations made in connection with a study for the Preservation of Niagara Falls included in Senate Document No. 105, 62nd Congress, 1st Session. (Chapter 3, including Plates 1 and 3.)

"Chapter 3. The Hydraulic Conditions.

"Lake Erie is a natural basin filled with water; the Niagara River is a notch or cut in its brim permitting definite quantities of water to spill out; and the water flows out here because it is the lowest place on the brim, and because it leads to lower levels, and seaward.

"The notch or sluiceway at the head of the river is in limestone hard enough to resist rapid wear under the influence of the running water. Because the dead water of the lake forms a settling basin, the water at the head of the river carries little sediment, and this accounts for the slight abrasive effect of the flow, and for the stability of this low rock barrier, wier, or dam whose integrity is essential for the retention of Lake Erie at its proper surface level. In discussing the hydraulics of the Niagara River, this low rock barrier, reaching from the head of the river to the International Bridge, will be spoken of as the initial weir.

"The river is flowing almost due north as it breaks out of Lake Erie. (See Pl. 1.) At the head it has the usual trumpet entrance, but narrows down in 1¼ miles to little more than 1,500 feet in width, with a natural depth of about seventeen feet and a velocity as great as 8 miles an hour. As it approaches the International Bridge 1¼ miles farther down, it grows a little wider, deeper, and slower. At the foot of Squaw Island it widens to 2,300 feet, and the first sharp descent of about five feet from the level of the lake is passed. Two miles farther down the river is split into two channels by Grand Island—the Canadian Channel about 10 miles long and the American or Tonawanda Channel about 13 miles long. From Squaw Island to the foot of Grand Island, and as far down as Welland River, the current is moderate and the river is navigable; in fact, the Welland River is a side entrance to the Welland Canal.

"The 'dead line,' marking the beginning of the dangerously swift water approaching the rapids, runs from Chippawa at the mouth of the Welland River across to the entrance of the Hydraulic Canal at Port Day. Along this line velocities run as high at 3½ miles an hour at ordinary stages, and in high water are greater. The uppermost cascades of the rapids approaching the Horseshoe Fall are about a mile below the 'dead line,' and the shallow water marking the brim of the upper river basin is little below Chippawa. From the uppermost cascades to the crest of the Horseshoe Fall is five-eighths of a mile.

"The cataract drops into a deep basin or pool where the current is moderate, with water as deep as 189 feet, and this Upper Gorge pool is navigable from near the cataract to Suspension Bridge, a distance of about 2 miles. At Suspension Bridge is the brim over which the water spills out of the Upper Gorge pool and makes the descent of the Whirlpool Rapids to the Whirlpool. The Whirlpool is another deep basin, the water having a rapid rotary motion. The water is spilled out of the Whirlpool basin over the brim at the head of the Lower Rapids; and at the foot of these rapids, from Lewiston and Queenston down, is the broad, still, deep, navigable river stretching in a straight reach of 7 1/16 miles to Lake Ontario.

"The profile of the river from Chippawa to Lewiston is shown on Plate 2.

"It is evident that the Niagara River is a series of basins or pools, linked by swift water or rapids, which form the sluiceways or spillways from these basins. There are four distinct basins (see Pl. 3) and as these have a most important bearing on the measurement of the river flow, and make the determination of diversion effects possible, the identity of each must be emphasized.

"Lake Erie is the initial or parent pool; from Squaw Island to the rapids above the Cataract is the second, or Grass Island-Chippawa pool; the Upper Gorge is the third pool; and the Whirlpool, the fourth. The peculiarity of these basins is that the height of the water surface near their outlets indicates with considerable precision the amount of water flowing through the river. Because of this fact it is possible, by painting certain graduations on gage boards fixed vertically at the proper elevation and placed in proximity to the crest of each weir, to make the water surface itself disclose the volume of river flow. If such a board were set in Lake Erie at the lighthouse on the north end of the breakwater, and the graduations were in units of a thousand cubic feet per second, each graduation would be a little over half an inch long. The graduations of the board set up in the second pool at Grass Island, or at Chippawa above the Upper Rapids, would have graduations a little more than half as large; at Suspension Bridge, in the third pool, the graduation would be about 1¼ inches long, and in the Whirlpool 1¾ inches.

"An increase in the river flow of 22,400 cubic feet per second at ordinary lake stages, which results from a rise in the water surface of Lake Erie of 1 foot, produces at Chippawa

and Grass Island a rise of 0.56 foot, of 2.29 feet at Suspension Bridge, and 2.47 feet in the Whirlpool.

"These pools are shown in Plate 3. Assumed stages of the several pools are indicated by the scales shown on the left-hand side of each gage board, and the corresponding river flow is shown by the scale on the right-side.

"That the water-surface elevations existing in these several pools should maintain certain definite relations to one another is not accidental, but depends on well-known hydraulic laws. Among hydraulic engineers it is a well known fact that a dam or weir with the water flowing over the crest forms an instrument by which the volume of flow may be measured. After a particular weir has been calibrated the elevation of the water surface, as shown by a water gage in the pool above the crest of the weir, gives the measure of the flow.

"In the case of the Niagara River the weirs are natural formations, and the term 'weir' is not technically precise. Nevertheless, they serve the same purpose as artificial weirs in forming pools by rock rims, or by constrictions. They enable calibrations to be made, so that the water-surface elevation of any pool indicates the corresponding volume of flow.

"The initial weir at the head of the river has a width of 1,690 feet, the width of the second weir at the head of the Cataract Rapids is 3,740 feet, the third at Suspension Bridge at the head of the Whirlpool Rapids 390 feet, and fourth at the head of the Lower Rapids, which is the outlet of the Whirlpool, is 390 feet. Comparing the length of the weir crest at the head of the Upper Rapids with that in the outlet of the Whirlpool, it is not difficult to understand the relative fluctuations of the river. The great length of the weir at the head of the Upper Rapids, 3,740 feet, permits the passage of an increased volume of flow by a small rise; while the short length, 390 feet, of the Whirlpool outlet weir chokes the flow and compels a very considerable rise before the area of outflow is sufficient to pass the additional water. This large movement in the Whirlpool makes the fourth weir an extremely sensitive measuring instrument, and for a similar reason at Suspension Bridge the vertical water movement is large also, and the senstitiveness of the third weir as a measuring instrument is likewise great. The weir at the head of the river has an intermediate length and the rise corresponding to an increment of flow is seen to be intermediate, one foot as against 0.56 foot for the second weir and 2.47 feet for the fourth weir.

The initial weir at the head of the river has a peculiarity not shared by the other three weirs, namely, that it is affected by backwater from the pool below, which reaches from the head of the Upper Rapids to Austin Street, Black Rock, at the foot of Squaw Island. The fall from Lake Erie to Austin Street has already been stated as in the neighborhood of five feet. The very extensive and careful measurements made by the Lake Survey in 1898 to 1900, pointed to the fact that the outflow from Lake Erie was increased about eight-tenths of 1 per cent. by lowering the water surface of the river at Austin Street, one-tenth of a foot, and subsequent investigations at the time of the July-August, 1908, shut down of the Niagara Falls Power Co., as well as certain slope observations, closely corroborate the earlier conclusions.

"While the lower river weirs are entirely free from backwater effect in the pools below them, the initial weir at the head of the river has this greater complexity, and it is because of this fact that the surface level of Lake Erie is affected by the diversion of water in the second pool lying above the first cascades of the Upper Rapids.

"Looking at the other three weirs of the river series from the lower level upward, it is very plain that no known elevation of Lake Ontario, or of the Niagara River at Lewiston, can have any effect whatever in the outflow from the Whirlpool. From Lewiston up to the Whirlpool is a distance of 3½ miles, with a rise of 47 feet. In this reach of turbulent rapids and swift water and some cascades, the possibility of backwater due to Lake Ontario's height is unquestionably absent. The height of the water surface in the Whirlpool is therefore dependent on the volume of river flow alone. In the winter season, however, ice in the rapids is not unlikely to create somewhat different conditions of outflow, and for this reason the ice period is not here considered. It is probable that small changes do occur from time to time in the river Reach between the Whirlpool and Lewiston, as well as in the Whirlpool Rapids reach from the Whirlpool to Suspension Bridge. The bottom, however, throughout these reaches is of rock which the current cannot easily move. As regards scour, the condition of the water entering the Whirlpool Rapids is very similar to that of water entering the river from Lake Erie. While the water is violently agitated at the foot of the Cataract, it afterwards passes slowly through the deep settling basin of the upper gorge, where particules detached by the impact of the cataract are precipitated.

"Whatever may be the permanence of the channels of these rapids for a long term of years, the fixity of conditions since water gages were established in the Whirlpool and at Suspension Bridge in 1906, is attested by the water-gage records themselves.

"From the Whirlpool through the Whirlpool Rapids to Suspension Bridge is a river reach of a mile with a rise of 48 feet, and this, like the Lower Rapids is a turbulent series of sluices and rips. That any backwater effect may proceed from normal conditions in the Whirlpool to affect the height of the water at Suspension Bridge and in the Upper Gorge pool is impossible.

"That the height of the water at the foot of the Cataract does not have any backwater effect on the river at the head of the Upper Rapids is manifest.

"The upper river pool terminated by the first uppermost cascades of the Upper Rapids, and of the American Channel, includes the intakes of the Ontario Co. on the Canadian side and of the two large canals on the American side. A nice question in backwater effect may seem to be presented by the locations of the intakes of the Electrical Development Co. and of the Canadian Niagara Falls Power Co. Between the intake of the Ontario Co., and the intake of the Electrical Development Co., is a descent of 23 feet, including four cascades; and from the intake of the Electrical Development Co. to the intake of the Canadian Niagara Falls Power Co. is a descent of 15 feet more, including one cascade. It is very certain that any diversion of water, or any small raising of the water at the last named intake, can have no possible effect on the elevation of the water above the first cascade or in the upper river pool. It is certain also, on the face of it, that any diversion made by the Electrical Development Co., or any small raising of the water at its intake will not effect the upper river above the first cascade. The very presence of the cascades themselves is evidence of water flowing sheer, presenting rather the effect of a free fall than of water passing over a drowned weir."

Also extract from Chapter, "The Outflow of Lake Erie," beginning on page 25 and ending on page 27, as follows:

In the whole length of the Niagara River (except for diversions) practical continuity of flow is in force. That is, the contributions of water entering by creeks or rivers between Buffalo and Youngstown are so trivial, compared to the great volume of river flow that under ordinary summer con-

ditions they may be neglected. Any evaporation from the river surface is also negligible.

It follows that the volume of flow under quiescent or normal conditions is the same for each cross-section of the river. If the volume of flow were measured simultaneously at Buffalo, Suspension Bridge and Lewiston, the results would be the same. The water entering the river at Buffalo passes out of the river at Fort Niagara neither appreciably increased nor diminished.

For this reason it does not make any great difference at what section the volume of flow is measured, except that it is desirable to make the measurements at such a point as will serve to give the most accurate results. A straight reach of river with a smooth bottom, together with a velocity of four or five miles an hour, a depth of 30 feet or more, and a fairly smooth, eddyless surface, presents excellent conditions, and better if the water is running faster below it.

A vertical plane perpendicular to the direction of the current cuts the stream in what is called the hydraulic section. Soundings taken at intervals from bank to bank along the line in which the plane intersects the surface, as every ten feet, develop the bottom profile. The area between the bottom and the water surface is the cross-sectional area. For purposes of current measurement, the river is conceived to be made up of a series of sub-streams flowing side by side, each perhaps 100 feet wide. The vertical line at the middle of each substream is the station, and at some fixed percentage of the depth below the surface on the station, as the four-tenths depth, is the controlling current-measuring point called the index.

The current is running slowly next to the banks and fastest out toward the middle of the river, and the plotted curve showing the velocities (for index depth) at various distances across the section is called the transverse curve of velocities. At different depths the current velocity is different, being swiftest near the surface and perhaps half as swift at the bottom. The plotted curve showing the velocity at a station for each tenth of depth is called the vertical curve of velocities.

Because, at varying distances from the bottom and from the banks, the velocity of water flowing straight and smooth is governed by the laws of fluid friction, no abrupt changes occur, except perhaps very close to the bottom or to the banks. The transition from the high velocity near the surface to the lower velocity a foot above the bottom is gradual,

so that the vertical curve of velocities is generally a smooth curve, and the curves at different stations show great similarity. That the forms of vertical curves in smooth stream flow adhere to type is well recognized, and the vertical curves of the Niagara River are closely approximated by those of the St. Clair and the St. Lawrence Rivers.

The transverse curve of velocities is likewise easy, and reproduces in general outline the bottom profile. The deepest water on the section is also likely to be the swiftest, and as the water grows shallower the velocities grow less. The orderly way in which water flows, with remarkable adherence to a fixed plan, makes the accurate measurement of the volume of flow easily possible.

The preliminary work in measuring the volume of flow consists in accurate soundings and a determination of the cross-sectional area of each substream; then the determination of the velocities at different points in each substream, as percentages of the velocity at the index. The index, which is midway of each substream and at three-tenths or four-tenths depth, is a sampling point for velocities to the extent that the velocity measured there is finally the key to the mean velocity in the whole substream. Before, however, a co-efficient is determined which will reduce the observed velocity at the index to the mean substream velocity, much preliminary work must be done in measuring simultaneously the velocity at the index and at other points in the substream. The possibility of a reduction co-efficient is due to the adherence of the different parts of the substream to fixed relative velocities. Some evidence of this law of stream flow is cited in the report of 1900, already referred to, page 5343. In interpreting this statement of fixed velocity relationships, conditions of river equilibrium are understood, and the measurements at the points must be of long enough duration to eliminate the flame-like spurting and lagging of the current threads characteristic of river flow. In arriving at the co-efficient of reduction, it is necessary also to measure the directions of the current, or its deviation from the normal to the section. The operations having in view the determination of the reduction co-efficients are called co-efficient work.

After the cross-sectional areas and the co-efficients are determined, a single velocity measurement at each of the station indexes constitutes a river traverse or discharge measurement. For each substream the volume of flow is the product of the index velocity multiplied by the reduction co-efficient,

and by the cross-sectional area, at the time of the measurement. The total river volume of flow is the sum of the volumes in all of the substreams.

While a discharge measurement is being made a water gage on the hydraulic section records the water surface elevation, as a basis for determining the cross-sectional areas at the time of the measurements. This is called the section gage. In the measurement of the discharge of the Niagara River at the International Bridge, a second water gage just above the head of the river records the level of Lake Erie. A third gage at Austin Street, Black Rock, records the level there, thus determining the backwater effect of the river below. The velocity measurements in the Niagara River work were made with current meters of the propeller-wheel type, and these were calibrated on still-water bases and subsequently in flowing water. The process of calibration is called rating. For detailed description of meter rating on a still-water base, and for much detail which cannot be repeated here, reference is again invited to the Report of 1900.

The measurements of the volume of flow of the Niagara River were made first at the International Bridge, where the downstream lower bridge chord defined the hydraulic section and the bridge itself served as an observing platform. The river flows in nine streams through the openings of the nine spans. The spans are numbered from east to west, span 9 being next to the Canadian bank. Spans 4, 5 and 6, have clear openings at the water line of about 235 feet, with depths reaching 50.7 feet, and together carry 73.1 per cent of the river flow. The remaining spans vary from 138.4 feet to 187 feet. For purposes of measurement each of the three long openings was conceived to be divided into three substreams, and each of the shorter openings into two substreams, making in all 21 substreams. The index at the stations was taken at three-tenths depth. The International Bridge Section, with the river broken up into nine streams, with the bottom and slopes around the piers somewhat ragged, and the piers themselves creating eddies, proved more complex than a section in the unbroken open river. This complexity made co-efficient work more laborious. The error likely to enter from the added complexity is discussed on page 5332 of the Report of 1900, and appears to be in the neighborhood of a half of 1 per cent.

Chapter VIII.

The Shutdowns of the Niagara Falls Power Co.

On May 13, 1908, the Lake Survey Office was notified by Mr. Philip P. Barton, General Manager of the Niagara Falls Power Co., that, to permit an examination of the east abutment of the upper steel arch bridge, where it was thought to have suffered from the wash of the tunnel discharge, this company would shut down its plant shortly after midnight of June 13.

As the shutdown was to cover a period of some hours, the opportunity to observe the rise of water surface following a return to the river channels of about 8,000 cubic feet per second of flow appeared of great importance. As the rise in the river, provided quiescent weather conditions prevailed, would conversely measure the lowering due to this diversion, elaborate preparations were made to test the rise at critical points, and also to measure the change in diversion causing this rise.

Box gages were set at the heads of each of the two large canals on the American side, to test at intervals the records of the self-registering gages maintained by the power companies. Another gage was set, as in 1907, on the hydraulic section in the Niagara Falls Power Co's canal. A box gage was set also at Prospect Point close to the crest of the American Fall, in the position occupied by the self-registering gage in 1907. To observe precedent conditions, readings at 10-minute intervals were taken on the gage at Prospect Point, beginning on the morning of the 13th, and, to secure a record of conditions during the shutdown and afterwards, were continued day and night up to the morning of the 15th.

To make sure of a record at Buffalo and at the foot of Austin Street, staff-gage readings were taken during the critical period to reinforce the self-registers. The gages at Niagara Falls were insured against stoppages by a constant patrol.

Current-meter measurements of the volume of flow in both large canals were made before the shutdown, as the gates closed, and after they were opened again.

Had the weather conditions remained good, even so brief a period as this would have given some valuable information, for, in addition to the shutdown of the Niagara Falls Power Co., the Niagara Falls Hydraulic Power & Manufacturing Co., had arranged to restrict its flow so as to permit the greatest possible change. Unfortunately, the results were of small value. The shutdown in the power canal began about mid-

night and was completed by 1:20 in the morning. The hydraulic canal, on the other hand, had not completed its partial shutdown before six o'clock Sunday morning. Meanwhile, a stiff southwest storm on Lake Erie arose about midnight and caused the water at Buffalo to rise a foot and a half by three o'clock in the morning. This rise in the lake, causing increased flow in the river and, therefore, greater heights at all points, is entangled with that coming from the shutdown, and the two cannot be separated. The rise on the crest of the American Fall between midnight and three o'clock was 0.1 foot. Up to two o'clock it was 0.06 foot, or three-fourths inch, and this, if attributable solely to shutdown, would be fairly corroborative of anticipated results.

The examinations of the June shutdown having shown the need of repairs on the abutment of the bridge and in the tunnel of the power company, a second shutdown of this company, aggregating practically ten days, was made in July and August. Considerable preparations were again made to make the most of this partial return of the river to a state of nature, and the observations were extended to incorporate very precise information of the influence, not alone on the river-surface levels, but also on Lake Erie's outflow. Early notification was sent to this office by the power company, and the hydraulic company offered its co-operation to the extent of a preliminary increase of flow, and a cessation, on Sunday, July 19, only, of the larger part of the flow of its canal.

The power company shut down at 1:30 on the morning of the 19th, and remained closed until 12:30 on the morning of the 28th, when power house No. 1, resumed, power house No. 2 remaining shut down.

On August 1, at 11:30 at night, the shutdown was again complete and remained so up to 7:30 in the evening of August 2, when both power houses resumed.

The shutdown was, therefore, practically complete on the nine days, July 19 to 27, and nearly complete on August 2, or ten days in all.

The mean condition of the river for these ten days of lessened diversion is compared with the river condition on six days preceding the shutdown, July 13 to 18, and on four days after resumption, August 3 to 6, making ten days in all of the condition of normal diversion.

During the ten days of diversion the mean water consumption of the two American companies was 7,850 cubic feet per second, and during the shutdown it was 1,640 cubic feet, a

change in consumption of 6,210 cubic feet. (See table 39.) The small diversions of these companies prevailing at this time were due to the existing business depression.

The average consumption of the Ontario Co. from July 13 to August 6, as derived from its curves of total load, using a co-efficient of 0.0866 to convert kilowatts to cubic feet per second, was less than 1,500 cubic feet, and was slightly less during the shutdown, owing to the lighter load of the three Sundays included, than in the six days before and four days following. During the shutdown a box gage was established just above the forebay of the Ontario Co. Taken in connection with the Chippewa gage, this gage was an index of the comparative flow over the water wall and through the conduit of this company, in the two periods.

Prior to the shutdown and after resumption the flow in the canals of the American companies was frequently measured with current meters, and during the shutdown of the power company the flow in the hydraulic company's canal was measured daily.

During the 5-day period, July 28 to August 1, while power house No. 2 was still shut down the flow in both canals was measured daily. The flow in the power company's canal was nearly equal to that existing when both power houses were in operation. For this reason the results of this period have small value and do not appear in this report.

During the 25-day period, from July 13 to August 6, self-registering gages were maintained in Lake Erie at Buffalo, and in the river at Black Rock, Schlosser's dock, Grass Island, Wing Dam, and Suspension Bridge; and on the Canadian side at Black Creek, Chippewa, Crest of the Horeshoe Fall, and in the Whirlpool.

During the shutdown, in order to insure observations in case of stoppages of the self-registering gage instruments, readings at 10-minute intervals day and night were made on staff gages in Lake Erie and at Austin Street, Black Rock and the patrol of the self-registers by inspectors was bi-daily or more frequent. No pains were spared to make the record complete and accurate. Additional staff gages were read at Prospect Point, on the crest of the American Fall, and in the canals of the two American Companies, and, as has been before stated, in the approach to the Ontario Company's intake.

During this 25-day period, to corroborate the values of the change in Lake Erie outflow shown by the Suspension Bridge

and Whirlpool gages, 50 measurements of the flow of the river were made at the International Bridge, Buffalo.

The many activities of this period kept a considerable party of civil engineers and assistants busy. In addition, a part of the staff-gage reading at Buffalo and at the Ontario Company's intake was done by an inspector employed by the American section of the International Waterways Commission.

The results of the shutdown are discussed in Chapters IX to XI, entitled "Effect on Lake Erie," "Effect on the Niagara River above the Upper Rapids" and "Effect on Rapids and Falls."

No photographs were made in this period because it was well known in advance that the small change in diversion would have no visible effect on the American Fall, and because increased water consumption by the Canadian Companies to supply the power company's customers with electric current during the shutdown would mask any small effect on the main rapids and Horseshoe Fall.

For this latter reason no gage readings were taken at Terrapin Point, and, except as confirmatory of results elsewhere, little weight has been given to the gage readings on the Canadian end of the Horseshoe Fall.

So far as effects on Lake Erie and the river above the rapids or on the American Fall are concerned, the diversions of the Electrical Development Co. or of the Canadian Niagara Falls Power Co., have no bearing. These two companies combined supplied, according to the total load curves furnished by them, an average of 7,110 kilowatts more during the 10-day period of the shutdown than during the 10-day period of comparison before and after the shutdown; and the production of this excess current meant an additional water consumption not exceeding 1,000 cubic feet per second. The Ontario Co., on the other hand, according to its total load curve, consumed less water by 100 cubic feet during the shutdown than in the period of comparison. This, as has been explained elsewhere, is because the shutdown period contains three Sundays when manufacturing plants were not running, while the period of comparison is all working days.

In discussing the change of flow in the Niagara in these two periods, the small difference in consumption indicated for the Ontario Co. is not considered, because changes in the water wasted over the water wall may exceed this amount and be of different sign.

The detailed results of the shutdown of July-August, 1908, are given in Table 39, and this needs some explanation.

River gauges: A (+) residual indicates that the river is higher than its normal height for the corresponding lake stage; A (—) residual indicates that the river is lower than its normal height for the corresponding lake stage.

Residuals of discharge are in cubic feet per second. A (+) residual indicates that the flow in the river is greater than normal for the corresponding height of Lake Erie. A (—) residual indicates that the reverse is true.

Diversions refer to those on American side only. That of the Ontario Power Co. was practically constant for this period.

It will be noticed that Lake Erie at Buffalo was at elevation 573.32 during the ten days of diversion and 573.10 during the shutdown, making the lake 0.22 foot low for the latter period. This difference in level, however, does not produce any error in the results because it is eliminated by reducing to a common lake-level plane. For each day the elevation of the water surface for that day's level of Lake Erie at Buffalo is computed for each gage by its equation of equivalent river heights. If the Chippewa gage on July 14 shows 0.08 foot higher than its computed height, a plus residual (+8) is set down. If on July 20 the river at Chippewa is shown by the gage to be 0.22 foot higher than its computed height, a plus residual (+22) is set down. The excess of the residual during this one day of shutdown over that of this day of diversion (22—8) shows that for exactly the same lake stage the river for the shutdown day is 0.14 foot high, and that is the evidence of these two days as to the effect of the shutdown. The mean residual during the diversion days subtracted algebraically from the mean residual during the shutdown shows, if plus, the rise, and if minus, the lowering due to the shutdown.

The equations of equivalent river height by which these residuals are derived are very exact, but if any small constant error should exist in them it is eliminated by the subtraction.

As, however, any error in the ratio of change at the river gages for a unit change of Lake Erie at Buffalo is not eliminated by subtraction, some discussion is needed to indicate how large it may be.

A gage was maintained at Grass Island in 1903, and the equation resulting from the observation was—

$$\text{Grass Island (1903)} = 560.826 + 0.543\ h \qquad (3)$$

in which h is the water-surface elevation of Lake Erie at Buffalo above 570. The ratio of river change to lake change is 0.543.

In 1907 a gage at the same place showed—

$$\text{Grass Island (1907)} = 560.528 + 0.555\ h \qquad (4)$$

For Lake Erie at stage 573 this gives the water surface at Grass Island as follows:

1903	562.45
1907	562.193

This shows a lowering between 1903 and 1907 of 0.262, or a little over three inches. This lowering is mainly due to the removal of the temporary diverting dam of the Ontario Co., the use of water by that company, and some increased diversions on the American side. The ratios, however, in the two

equations, 1903, 0.543, and 1907, 0.555, differ by but 0.012 foot, or one-eighth inch, for a change of a foot at Buffalo.

A combination of the 1903 and 1907 observations gives a ratio 0.556, or roundly 0.56, which has been used in the reductions and in this report.

As the Chippawa gage is just across the river in the same pool, its equations are of interest in relation to the ratio of change.

The 1906 gage at Chippawa gives—

$$\text{Chippawa (1906)} = 561.240 + 0.549\ h \qquad (5)$$

No separate equation is derived for the 1907 observations, but for the observations of 1906 and 1907 combined the following equation results:

$$\text{Chippawa (1906-7)} = 561.228 + 0.557\ h \qquad (6)$$

For Lake Erie at 573 these equations give:

Chippawa (1906) 562.887
Chippawa (1906-7) 562.899

The ratio, 0.56, identical with that at Grass Island, has been used in the reductions and in this report.

The four derived ratios summarized are:

Grass Island (1903) 0.543
Grass Island (1907) ..... .555
Chippawa (1906) ..... .549
Chippawa (1906-7) ..... .557

There seems little doubt about the propriety of the ratio 0.56, representing as it does the later conditions. However, if 0.50 were the proper ratio instead of 0.56, the error entering into the results in this pool during the shutdown would not exceed (0.22×0.06), or 0.013 foot.

The 1906 observations gave for the Willow Island gage at the head of the American Channel a ratio of 0.422, and the 1907 observations for Wing Dam a little further downstream give 0.412.

In the Whirlpool the following variations of ratio are shown:

1906 ..... 2.478
1907 ..... 2.482
1906-7 ..... 2.458

and the ratio used in reductions is 2.47.

For Suspension Bridge the range of ratios is greater:

1906 ..... 2.285
1907 ..... 2.375
1906-7 ..... 2.286

and 2.29 was accepted as a proper ratio.

At Austin Street, Black Rock, the observations show ratios as follows:

1903	0.830
1907	.802
1899, 1900, 1903, 1907	.821

and 0.82 is accepted as correct.

The ratios at Prospect Point, Terrapin Point and at the Canadian end of the Horseshoe Fall are likely to have errors as great as five per cent. or more of their values, because the ratios depend on the records of a few months only.

TABLE 40. COMPARISON OF DAILY MEAN WATER-SURFACE ELEVATIONS OBSERVED AND COMPUTED

Date 1908	Buffalo	Austin Street			Schlossers Dock			Chippawa

[1]Shutdown. [2]Partial Shutdown.

The residuals of Tables 39 and 40, therefore, in the conversion processes necessary to make the results comparable, have not been subjected to distortion.

The mean decrease in the diversion in the two 10-day periods compared was 6,210 cubic feet per second. The first effect of this was to add that much water to the flow over the Rapids, and this required a rise in the Chippawa-Grass Island pool of 0.117 foot as shown at Chippawa; this backed up the river so as to cause a rise at Austin street, Black Rock, of 0.028; and this in turn lessened the outflow from Lake Erie, as indicated by the gages at Suspension Bridge and in the Whirlpool by 600 cubic feet per second. The final outcome was that the change in flow over the Rapids was 6,210 less 600, or roundly 5,600, and the bulk of this went over the main rapids. At the same time, the Electrical Development Co. and the Canadian Niagara Falls Co. assuming part of the burden laid down by the Niagara Falls Power Co. which had shut down, took from the main rapids perhaps 1,000 cubic feet, giving a probable excess flow over these rapids and the Horseshoe Fall of only 4,500 cubic feet per second.

In order, therefore, to derive the final effect of a diversion of 10,000 cubic feet in the American Canals, the difference in the residuals shown in the summary must be multiplied by 10,000/5600,, or by 1.79. The effects of 10,000 cubic feet so diverted are given in the discussion in specific chapters.

The agreement of the residuals from day to day is sufficient warrant that heavy rainfalls or wind storms did not interfere with the essential fairness of the test; but to make the evidence complete, the following abstracts furnished by the weather observer at Buffalo, Mr. D. Cuthbertson, are included in this report:

TABLE 41.—WEATHER CONDITIONS, 1908.

The fact that Lake Erie, with its 240 miles of length, was but 0.22 foot higher during the 10-day period of diversion than during the shutdown indicates the small effect of the southwest wind, with its higher velocity, as opposed to the north and east winds of the shutdown period.

The precipitation, except as it might cause a slight rise in Chippawa Creek, is of little moment. The high precipitation of July 17 and 18, during diversion, was probably still running off on the 19th and 20th, and therefore affected both periods, and its influence is largely eliminated by subtraction.

Note.—In Appendix 3, the following tabulations of data are given:

Table 42—Volume of river flow by three weirs.

Table 43—Variation at different gages.

Table 44—Flow in power canal for shutdown periods.

Table 45—Flow in hydraulic canal for shutdown periods.

Table 46—Water-surface elevations at various gages during shutdown period."

Extract from the same document (page 50) as follows:

"At the time of the shutdown of the Niagara Falls Power Co. in July-August, 1908, the change in the flow over the Rapids was the amount due to the return to the river of the diversion of 6,210 cubic feet per second, less 600 cubic second-feet decrease in Lake Erie outflow, or 5,610 in all. As at that time the normal river flow was upwards of 224,000 cubic second feet, the change in the river flow was only 2½ per cent. While this is not a large quantity to predict results upon, it is a full third of existing local diversions. (See Table 39, Chapter VIII.)

"The lowering at Chippawa due to this diversion was proved by the shutdown to be at the rate of 0.21 foot for a diversion of 10,000 feet, or 0.04 foot (½ inch) less than computed from the observed equivalent river heights. At Grass Island it was 0.40, or 0.15 foot more than shown by equivalent river heights, but an excess was expected here as a localized effect."

Extract from the same document as follows (page 59):

"To verify the cross-sectional area derived by the methods described above, Section No. 1 was sounded with a 95-pound projectile-shaped cast-iron weight. The area resulting from these soundings showed for identical gage heights about ⅓ of 1 per cent. larger than by the more precise method of level and rod."

Extract from same document Chapter 15, current meter tests (pages 72 to 74, inclusive), as follows:

"Chapter XV. Current-Meter Tests.

"The hydraulic work of the Lake Survey on the outflow of the Great Lakes depends fundamentally for its accuracy on the proposition that the Haskell Current Meter rated on a still-water base gives the true velocity of flowing water. The work of the Lake Survey up to the time of the experiments here briefly described contains no demonstration on this vital points.

"On the face of it, an efficient rating on a still-water base, in which a mass of water is at rest and the instrument is passed through it, should show the same wheel revolutions as a current rating, in which the meter is at rest and the water flows through it. It would seem to be merely a matter of relative motion between instrument and water. However, it is claimed that the impact on the wheel vanes of the particles of flowing water, owing to the intricate nature of their movements, does not have the same effect in wheel revolutions

as the impact between the vanes and the inert particles of still water.

"In submitting formulas for discharge of the Niagara and St. Lawrence Rivers, it seemed proper to apply a correction for instrumental error, if such error existed, and these experiments were made to determine this point.

"The Haskell Current Meters, one of type A, called L. S. 4A, and one of type B, L. S. 1B, were carefully rated on a still-water base. The methods used were similar to those used in rating meters for the discharge work in the Niagara and St. Lawrence Rivers, and described in the Reports of the Chief of Engineers, United States Army, for 1900 and 1901, except that the meter was suspended from the deck of a light catamaran, whose hulls were of 8-inch diameter cedar poles, with a clear width of 12 feet between hulls.

"Each meter was rated three times, and the rating equation is derived from all observations corresponding to the river velocities of the current rating.

"In the still-water rating, a 200-foot base was used, marked by beads soldered on a galvanized-iron wire. This wire was stretched taut over the still water, and acted in addition as a guide for the catamaran.

"The current rating of the meters was done in the Detroit River just above the Lake Survey depot at Fort Wayne, and about 200 feet out from the dock line.

"A section of the steel pontoon sweep was suspended in the current, held by a head anchor. A second section was suspended tandem from the first by two galvanized-iron wires, one on each side, having beads soldered on them 200 feet apart. The starboard wire formed the current rating base. The length between beads of the wires was measured, before and after the tests, by a steel tape.

"The sweep catamarans have decks that overhang at the sides the cylindrical steel hulls. These overhangs were extended so as to drop the meters into the water 12 feet outside the starboard hulls, in order to place the instruments where the current lines would be entirely clear of hull influences.

"The 4A meter, was placed abreast the zero bead on the upper catamaran; the 1B meter was about five feet downstream from the 200-foot bead on the lower catamaran. The axes of the meter wheels were set 1 foot below the water surface.

"The two catamarans hanging fair with the current

aligned the meters so that the current threads passing the first passed close to the second also. The catamarans showed little movement, either sidewise or streamwise.

"As doubt exists as to whether a float travels at the same speed as the water in which it is immersed, and as a float must penerate the surface skin and be in some measure affected by the wind, it seemed best to avoid floats, and to make visible a ball of the water itself, so that its transit between the two terminal beads could be timed. It was found that about four ounces of a strong fluid, bluing, or a strong solution of aniline red, injected into the river at a depth of about a foot, would color a ball of water perhaps a foot in diameter at the start, which held together so that about 70 seconds later it would complete the transit of the 200-foot base, with a size not often more than double, and still a fairly compact mass of color.

"The colored water was injected about five feet upstream and a little to one side of the upper meter, 4A, using a small bicycle pump, pointed downwards and moving at the speed of the water as closely as it could be followed. When the center of the ball of color passed the initial bead of the base wire, the registration of both meters was started by pressing the stems of two stop watches. When its center reached the 200-foot bead, its transit was signaled and both registers were thrown out of circuit by stopping the stop watches. The total number of wheel revolutions for each observation, the transit time of the fluid, and its path were noted.

TABLE 66.—TESTS OF ACCURACY OF HASKELL CURRENT METERS L. S. 4A AND L. S. 1B IN DETROIT RIVER.

Number of observation. a	Date. b	Time of day. c	Velocity (feet per second). By meter 4A. d	By meter 1B. e	Mean by meters. f	By fluid transit. g	Residuals. f-g

Still water base and current base 200 feet long. Current flows S. W.
June 1—Weather fair. Wind 4 to 6 miles per hour from W.
June 2—Weather fair. Wind 10 to 12 miles per hour from N. N. W.

"The 76 observations of Table 66 show the result in detail. The velocity of the current as shown by the color fluid is taken as the true velocity and is given in column g. The velocity of the current as shown by the meters is given in columns d and e and the mean velocities shown by the two meters in column f. The mean velocity shown by the fluid and by the mean of the two meters for the 76 observations is practically identical—2.862 and 2.859 feet per second.

"On June 1, 44 observations showed a mean velocity of 2.818 feet per second by the fluid and 2.806 by the meters, the meters giving a lower velocity by nearly ½ of 1 per cent. On June 2, 32 observations showed a mean velocity of 2.922 by fluid and by the meters 2.933, the meters giving a higher velocity by about ½ of 1 per cent. These small divergencies are the expected errors of observations characteristic of hydraulic work. Individual observations show larger divergencies, coming from fluctuating velocities.

"The tests demonstrate conclusively the correctness of the indications of the Haskell meters.

"The 4A meter rated in these experiments was the meter most largely used in the measurements of the Niagara and St. Lawrence Rivers, and the 1B meter was used in the lat-

ter river. Both of these meters were used in the measurements of the flow in the Niagara Falls Power Co.'s canal (see Chapter XII) and with velocities close to those of the tests of 1906.

"The correction for instrumental error is taken as zero."

Letter from Major Charles S. Bromwell, U. S. Engineer's Office, Chicago, to Thomas A. Smyth, President Sanitary District, dated February 24, 1913, as follows:

"Engineer Office, United States Army.
509 Federal Building.
Chicago, Illinois, Feb. 24, 1913.

Mr. Thomas A. Smyth,
President, Sanitary District of Chicago,
American Trust Building,
Chicago, Ill.

Dear Sir:

"I am directed by the War Department to notify you that measurements made by the Engineer Department during January indicate that since the Secretary of War's decision of January 8, 1913, you have been diverting from Lake Michigan more water than the 4,167 second feet authorized by the existing War Department permits.

"Your attention is invited to Section 10 of the Act of March 3, 1899, which is being violated by such diversion, also to the provisions of Sections 12 and 17 of the same act, a marked copy of which is inclosed.

"Kindly advise this office what steps, if any, you propose to take to keep future diversions within the limits of the existing War Department permits and how soon such reduction of diversion may be expected.

"I have also to inform you that a continuation of the excess diversion may require action by the United States District Attorney.

Very respectfully,

C. H. B.
Major, Corps of Engineers.

Letter from Thomas A. Smyth, President Sanitary District to Major Charles S. Bromwell, dated February 27, 1913, as follows:

"Letterhead of
The Sanitary District of Chicago
American Trust Building.

February 27, 1913.

Major Charles S. Bromwell,
Corps of Engineers, U. S. A.
Federal Building, Chicago, Ill.

Dear Sir:

"I am in receipt of your favor of the 24th instant, concerning the diversion of water from Lake Michigan through the Channel of the Sanitary District.

"As a number of the members of the Board will be out of town during the next two weeks, I have called a meeting of the Board for the 13th prox., at which time your letter will be placed before them for consideration and prompt reply.

Yours very truly,
(Signed) THOMAS A. SMYTH,
President.

A true copy."

Letter from Major Charles S. Bromwell to Thomas A. Smyth, dated March 15, 1913, as follows:

"Engineer Office, United States Army,

U. S. Engineer Office
Chicago, Ill.
March 22, 1913.

H. P. Whitaker, President.
George W. Swett, Manager.
Major Charles S. Bromwell,
Corps of Engineers, U. S. A.,
Federal Bldg., Chicago, Ill.

Dear Sir:

"I have before me your letters of February 24th and March 15th, 1913, respectively, addressed to Thomas A. Smith, President of the Board of Trustees of the Sanitary District of Chicago. Also a copy of the letter of President Smith to you dated February 27, 1913.

"The Board of Trustees took up for consideration your various communications and the subject matter therein referred to at a meeting of the Board held on March 11, 1913, and I was directed by resolution of the Board to reply to your letter of the 24th. However, on the morning of the 12th I was compelled to leave Chicago for New York where I have been since and am now engaged in the taking of testimony in the case of the United States of America versus The Sanitary District of Chicago. Hence, the delay in answering your letter.

"The suit above referred to was filed by the United States some time in the year 1908 in the District (then Circuit) Court of the United States for the Northern District of Illinois to enjoin the Sanitary District from constructing a channel known as the Sag Channel from the Calumet River to a

point on the main channel of the Sanitary District at Sag, and also to enjoin the District from reversing the flow of the Calumet River through the proposed new channel, and from taking the waters from Lake Michigan for the purpose of diluting the sewage of the Calumet District immediately south of the City of Chicago—in so far as such withdrawal might increase the amount of water that the Sanitary District had been theretofore authorized to take by the Secretary of War, etc., etc. This new channel is an adjunct to the main channel and is designed to serve the population of the Sanitary District in that portion of the district known as the Calumet region. One of the legal questions involved is, that the State of Illinois has the right to provide for the health of its citizens in the manner that it has; that the United States has not interfered and could not interfere with the right of the sovereign state to reasonably provide for the preservation of the lives and health of its citizens.

"The amount of water proposed to be diverted through the Sag Channel was approximately 4,000 cubic feet per second; that was at that time the capacity of the proposed channel. On June 30, 1910, while said suit was pending the Sanitary District was granted a permit by the Secretary of War to complete and construct the new channel and to reverse the flow of the Calumet River, and to take water from Lake Michigan through this new channel, provided, however, that the water that might be taken through the new channel and that taken through the main channel should not in the aggregate exceed the amount authorized by the Secretary of War. Upon the issuance of this permit of June 30, 1910, the Sanitary District entered upon the construction of the Sag Channel, and has up to the present time expended and contracted to expend upwards of several million dollars in its construction.

"You are no doubt aware that the International Waterways Commission by its report of 1907 recommended that no question be raised as to the right of the Sanitary District to flow through its channels for sanitary purposes at least 10,000 cubic feet of water per second, etc., etc. You are likewise probably aware that the Sanitary District under its Organic Act of 1889, commenced the construction of its channels through which it was to flow the waters of Lake Michigan for the purpose of diluting the sewage of the inhabitants of the Sanitary District; that on January 17, 1900, after approximately ten years devoted to construction work, and after the expenditure of many millions of dollars the main

channel of the Sanitary District was completed and the waters of Lake Michigan from that time on has flowed through the main channel into the Des Plaines River in quantities at most times sufficient to dilute the sewage in accordance with the specific provision of the Organic Act.

"Until the decision of the Honorable Secretary of War of January 8, 1913, it was the general belief that the Secretary of War would without question formally consent under present existing conditions to the taking of water up to at least 10,000 cubic feet per second from Lake Michigan through the channels of the Sanitary District.

"The Act under which the Sanitary District is organized and under which it is now operating makes it mandatory upon the Trustees of the Sanitary District to cause not less than 20,000 cubic feet of water per minute for each 100,000 of the population of the District to flow from Lake Michigan through its channels. The population of the District is such that to comply with its organic law, it is necessary that the Board of Trustees cause more than 4,167 cubic feet of water per second to flow through the channels of the Sanitary District. That condition has existed for a number of years past and the Sanitary District has been flowing through its channels sufficient water to dilute the sewage pursuant to its Organic Act (20,000 cubic feet per minute for each 100,000 of population). The Sanitary District cannot either under the law of its creation or if it intends to preserve the health of the inhabitants of the District reduce that flow.

"I have at some length pointed out to you the facts with most of which no doubt you are familiar so that the situation in which the Sanitary District is now placed may be fully considered by you.

"The Board of Trustees of the Sanitary District appreciate their responsibility in the matter. It is their desire that the rights of the Sanitary District be finally determined. With this in view, and inasmuch as the suit now pending relating to the Sag Channel involves issues which are somewhat similar to the questions now involved in the interrogatories propounded in your two letters, I respectfully suggest that the bill of complaint in the case of the United States vs. Sanitary District now pending be amended or a supplemental bill filed so that all the issues above referred to may be settled and promptly adjudicated. A great deal of testimony has been already taken, all of which will apply to the issues that would be raised by the proposed amended proceedings. A great deal of time, work and trouble would be saved

by pursuing the method I suggest and the Sanitary District will co-operate to speedily make up and try the issues upon the issues which may be presented by the amended or supplemental bill proposed, and will also stipulate that all testimony thus far taken, be treated as having been taken in the amended proceeding.

"I respectfully request that before any definite conclusion is reached by the Government with reference to these suggestions that a conference be arranged between the representatives of the Sanitary District and the Government at such time and place as may be convenient to the Government representatives.

Very respectfully,

EDMUND D. ADCOCK,

Attorney for the Sanitary District of Chicago."

Mr. Wilkerson: Referring to the notice served by counsel for defendant as to exhibits to be submitted on behalf of defendants, pursuant to stipulation of November 16, 1914, the United States reserves the right to specify such further documents or parts of documents as may be pertinent to any matters covered by subdivisions 3 and 4, of the paper entitled, "Memorandum of Documents to be referred to and exhibits to be submitted on behalf of defendants as further evidence in this case," served on counsel for the United States on December 6, 1914. This reservation is made because the time within which defendant is to specify particular documents has been extended by agreement until December 21, 1914, at which time the complainant is to present oral evidence concerning certain documents, in accordance with said stipulation of November 16, 1914.

Mr. Adcock: I offer in evidence on behalf of the defendant the following:

Extract from report of Mr. L. C. Sabin, July 1, 1900, Appendix III, Chief of Engineers, Report, Vol. 2, part 8, at p. 5401:

"The effect of withdrawing from Lake Michigan-Huron a certain amount of water through an independent outlet may now be determined within the limits of accuracy of our discharge equation. It has been said that the true discharge equation is probably of a higher degree than the first. A given change in stage at high levels would doubtless result in a greater change in discharge than at low levels. Consequently the continuous withdrawal of a fixed amount per second would effect a greater subsidence of lake level in low stages than in high stages. Considering the increment of discharge per foot rise in stage to be constant and equal to 19,030 cubic foot-seconds, the ultimate effect of withdrawing, say, 10,000 cubic foot-seconds, through an independent outlet will be to lower Lake Michigan-Huron 10,000÷19,030 or 0.525 foot, about 6¼ inches. If in very low water the increment of discharge becomes as low as 18,000 cubic foot-seconds the effect at low stage would be about 0.55 foot; and if at high stages the increment becomes as high as 22,000 cubic foot-seconds, the effect on the high stage would be 0.45 foot. When the lakes are below the mean stage of ultimate effect of the withdrawal of 10,000 cubic foot-seconds is probably not less than a half a foot.

"The area of Lake Michigan-Huron is, approximately, 45,314 square miles. A discharge of 10,000 cubic foot-seconds is equivalent to 0.0205 foot depth over the entire lake surface. The rate of fall, then, due to withdrawal of this amount of water alone would be 0.0205 foot per month, and to lower the lake 0.525 foot would require 25.6 months; but as soon as the lakes begin to fall on account of this additional discharge the discharge through the natural outlet will be diminished on account of the lower stage, and the rate of fall will thereby be diminished. The mathematical express of this law, giving the net change after months, is rather complicated and need not be given here. The results derived from it are given in the following table."

"Resolution Passed by the Forty-Fourth General Assembly, Special Session, 1906.

"Whereas, the Congress of the United States is now considering the report of the International Waterways Commission; and

"Whereas, said report contains a recommendation that the amount of water to be diverted from the Great Lakes through the Chicago Drainage Canal be limited to ten thousand (10,000) cubic feet per second; and

"Whereas, said limitation would in the future render futile the expenditure of fifty million ($50,000,000) dollars already expended by the Sanitary District of Chicago, and render impossible the completion of said project, and endanger the health of the people of Illinois and of the City of Chicago; and

"Whereas, the amount of water to be diverted for domestic and sanitary purposes should, under no circumstances, be limited by a treaty with a foreign power, or by any legislation to be enacted by Congress, thus placing the Sanitary District of Chicago—organized to preserve the health of the people—upon the same plane as commercial enterprises organized for private gain; now

"Therefore, be it resolved, by the Senate of the Forty-fourth General Assembly of the State of Illinois, convened in extraordinary session, the House of Representatives concurring therein, that in any treaty to be hereafter entered into, no statement whatever binding the trustees of the Sanitary District of Chicago shall be made, and the local conditions of such canal and the volume of water to be accommodated therein should be left wholly and solely to the regulation of the Federal Government, as the conditions of the canal's drainage may require; and

"Be It Further Resolved, that in any legislation to be hereafter enacted by Congress a provision should be included permitting the Sanitary District of Chicago to use such water as may be necessary in the discretion of the Secretary of War, and such legislation, if any, should be specifically provided that that portion of the report of the said International Waterways Commission referring to the Sanitary District of Chicago and the amount of water to be diverted through its channels should be entirely ignored; and

"Be It Further Resolved, that the two Senators and the members of Congress representing this state be and they are

hereby respectfully requested to do all in their power to incorporate the provision above referred to in any legislation to be passed by Congress, and prevent the incorporation of any statement in any treaty to be entered into with a foreign power placing any restriction upon the amount of water to be withdrawn through the Drainage Canal of the Sanitary District of Chicago; and

"Be It Further Resolved, that a copy of this resolution be forwarded immediately to the Secretary of State, to each Senator and Representative in Congress from this state, and to the President of the United States."

Mr. Adcock: I desire to offer in evidence all papers and documents offered for identification, or other documents, copies of which appear in the record, and not formally offered; and I desire that the documents which have been marked for identification, and bearing an identification number, may be considered as offered.

Mr. Wilkerson: If there happens to be any document which is offered, which is not copied in the record, it is understood you will give it to the Commissioner, so it will be printed. In other words, we want everything in the case in the printed record.

Mr. Adcock: I am not offering anything that does not now appear in the printed record. I simply make this offer in order to clear up any possible technicality as to whether the documents which were referred to by the witnesses and printed in the record, or identified by the witnesses, were not formally offered in evidence.

Mr. Wilkerson: There is not now in the record anything that is not printed, and that we have not used in our discussions of the case.

Mr. Adcock: No; everything is in the printed record now.

Saturday, December 19, 1914.
12:00 M.

Present:
Mr. Wilkerson, on behalf of the United States.
Mr. Adcock, on behalf of the Sanitary District.

The evidence of ISAAC DE YOUNG taken, so far as time is concerned, by stipulation today, instead of on last Wednesday.

ISAAC DE YOUNG, a witness called in rebuttal on behalf of the Government, was first duly sworn and testified as follows:

Direct Examination by Mr. Wilkerson.

Q. Please state your full name to the Commissioner?
A. Isaac DeYoung.
Q. Where do you live?
A. Sault Ste. Marie, Michigan.
Q. What is your occupation?
A. Civil engineer.
Q. In what service are you engaged?
A. U. S. War Department.
Q. Are you connected with the Lake Survey?
A. No.
Q. You are connected with what branch of the War Department; who is your immediate superior?
A. Engineer Department. My immediate superior is Mr. L. C. Sabin.
Q. How long have you been in the Government service?
A. Since 1901.
Q. What was your preparation before you went into the Government service, briefly?
A. Graduated from the Chicago Manual Training School and the University of Michigan.
Q. And you went directly after your graduation into the Government service?
A. No, sir, I was employed with the Big Four Railway about three or four months.
Q. And by any other companies?
A. Then from there, I was employed by the Michigan-Lake Superior Power Company, Sault Ste. Marie, Michigan.
Q. For how long?
A. 1898 to 1901.

Mr. Wilkerson: I will say that this evidence is directed to and is in connection with the Statistical Report of Lake Commerce for the season 1913, which is specified and offered in evidence.

Q. Referring specifically, Mr. DeYoung, to the canals at Sault Ste. Marie, have you had occasion recently to make any survey that has had to do with the Poe Lock?
A. Yes, sir.

Q. When was that survey made?
A. During November.
Q. 1914?
A. 1914.
Q. State generally what the nature of the survey was?
A. We had a diver cleaning off the sill preparatory to closing the locks, and while we had a diver down, we had him hold the sounding pole on the lower platform entering the lock; and we took several soundings on the sides and in the center of the lock; and the rod held was read by engineers' level.
Q. As to the elevation of the platform above the floor of the lock what did you find?
A. We found that on the sides the platform was not worn down from the passage of boats, but in the center it was worn slightly.
Q. How much?
A. Oh, I should judge about a half an inch.
Q. And as to the places which were not worn, as to their elevation above the floor, what did you find?
A. That was found to be the same elevation as the floor of the lock.
Q. And in the middle, it was worn down about half an inch?
A. About half an inch.
Q. Just where is that platform with reference to the floor of the lock?
A. The platform is partly outside of the masonry, the lower end of the masonry of the lock. It is separated by the two surface gates, lower surface gates.
Q. Is the platform below the lower guard gate?
A. It is.
Q. It is the only platform there is in that particular vicinity?
A. Yes, sir.

Cross-Examination by Mr. Adcock.

Q. What is your title there, Mr. DeYoung?
A. U. S. Assistant Engineer.
Q. What are your duties?
A. My duties have been designing lock gates and immediate charge of construction of the east approach to the locks, —dredging.

Q. Entirely engineering matters?
A. Entirely engineering.
Q. You were not connected with the War Department, at the time the Poe Lock was built?
A. No, sir.
Q. Do you have anything to do with the operation of the lock, directly?
A. Operating, and care only in connection with repairs.
Q. The operation of the lock and the passing of boats through the lock and so forth, that is done by somebody else besides you, isn't it?
A. Yes, sir.
Q. Did you make these soundings personally?
A. No, sir; under my immediate supervision.
Q. Were you present when the—
A. No, sir.
Q. Who did make the soundings?
A. Inspector Owen Frederick.
Q. Did you make any examination of the notes, field notes, that were made by the engineers who made this survey?
A. I examined them after they were made.
Q. You were not present at all when that was done?
A. No, sir.
Q. Do you know the elevation of the top of this platform that you speak of, as compared with the elevation of the top of the lower miter sill of the Poe Lock?
A. I don't think I do. I think, however, it is the same elevation.
Q. That is only an opinion that you have?
A. Yes.
Q. You don't know anything about it?
A. No, sir.
Q. Did you ever examine the plans under which the Poe Lock was built, particularly referring to this platform?
A. I have examined them, not particularly. I may say here that the plans are not very complete that we have in the office, in connection with the Poe Lock.
Q. So you never made any examination of those plans to determine the elevation of the top of this platform as compared with the elevation of the top of the lower miter sill of the Poe Lock as shown by those plans,—construction plans?
A. I have examined the plans in that connection but I don't remember exactly what I saw. The plans are very—they show—

Mr. Adcock: I move to strike out what they show. Don't say what they show. I want to get what you know.

A. What is the question again?

Q. (Last question read to the witness.)

A. I have examined those plans, but I don't remember now the relative elevations.

Q. Did you receive any instructions from anyone with reference to making a survey of the lock there; that is before the survey was made?

A. No, sir, only to make the survey.

Q. From whom did you receive that instruction?

A. Mr. L. C. Sabin.

Q. What did he say about it, did he write you a letter?

A. No, sir.

Q. Just told you that?

A. His method of giving instructions is by scrap notes.

Q. Did he say why he wished you to make the survey?

A. No, sir.

Q. What time in November did you make the survey?

A. I don't remember.

Q. What day?

A. I don't remember the date.

Q. Was it before or after the 16th of November?

A. I think it was after the 16th.

Q. Do you know how long?

A. Perhaps I might refresh my recollection.

Q. You know Thanksgiving day was about the 24th?

A. Yes.

Q. Was it after Thanksgiving?

A. It was before Thanksgiving, I am pretty sure.

Q. It was before, two or three days before? It was between the 16th and Thanksgiving day?

A. As far as I remember, yes, sir.

Q. You were first assistant to Mr. Sabin from 1900, were you?

A. No, sir.

Q. You never knew of a survey of this kind being made before, did you?

A. Yes, I do. There was a survey made of the east approach to the lock, taking 10 by 10 soundings, and the soundings extended up into the lock. These were rough, from water surface levels.

Q. Only?

A. Yes.

Q. So you would not obtain very accurate results in that way?
A. They could be taken within one-tenth of a foot.
Q. Did you make those soundings?
A. No, sir.
Q. Did you ever examine the notes of those soundings?
A. No, sir.
Q. When were they made?
A. I think they were made in 1904.

Re-direct Examination by Mr. Wilkerson.

Q. Is the miter sill the same elevation as the floor of the lock?
A. I think it is.
Q. Mr. DeYoung, I understood you to say you were in immediate charge of the survey?
A. Yes, sir.
Q. The work was done by engineers who worked under your direction?
A. Yes, sir.
Q. You took their reports?
A. Yes, sir.
Q. And from the reports made to you in this regular course of business, you make your statement that the platform is not elevated above the floor?
A. Yes.
Q. That is right, is it?
A. Yes, sir.

Re-cross Examination by Mr. Adcock.

Q. You were not present when the soundings were made or the survey was made?
A. No, sir.

Further Re-direct Examination by Mr. Wilkerson.

Q. When you say you were not present, you mean you were not actually on the ground?
A. I was not right there at the level.
Q. Where were you?

A. I was in the office.
Q. These men reporting to you right along?
A. I examined the notes.
Mr. Adcock: After the survey was made.
A. You probably understand how it is done.
Mr. Wilkerson: Describe how it is done so that we will get it into the record.
A. The level being set up, you read the bench mark of which we know the elevation, and then we read on the rod which shows the elevation of the bottom of the rod. If I had been right there at the level I would not have known any more about the accuracy of it than I would have if I had been right there in the office, not taking the notes.
Mr. Adcock: Q. How many men were there engaged in making this survey to determine the elevations,
A. There was the diver, the instrument man and the rod reader.
Mr. Wilkerson: We reserve the right at any future time to have the plans to which Mr. Ripley referred incorporated into the record.
Mr. Adcock: Q. How long ago did you make an examination of the notes of the survey of 1904?
A. I had the plans out some time during the last month.
Q. The last month?
A. Yes.
Mr. Wilkerson: Q. This platform has not been rebuilt since you have been there, has it?
A. No, sir.
Mr. Wilkerson: That is all.
Mr. Adcock: That is all.

TABLE SUBMITTED BY DEFENDANT SHOWING EXPENDITURES ANNUALLY FROM 1890—1912 INCLUSIVE, ETC.

EXPENDITURES BY THE SANITARY DISTRICT OF CHICAGO.
Cost of Works for Sanitation up to Dec. 31, 1912.

1890	$ 67,963.38	
1891	144,870.38	
1892	980,481.45	
1893	3,631,674.03	
1894	5,909,921.93	
1895	6,764,139.03	
1896	5,048,378.02	
1897	3,195,592.00	
1898	1,876,625.30	
1899	3,967,258.40	
1900	2,618,141.25	
1901	1,225,682.07	
1902	2,007,410.62	
1903	2,011,672.37	
1904	1,635,314.50	
1905	2,770,052.56	
1906	1,568,251.23	
1907	1,931,703.70	
1908	1,268,502.27	
1909	2,044,755.68	
1910	2,396,700.65	
1911	830,554.28	
1912	544,418.86	
		$54,441,676.00
Estimated cost in 1913 and 1914, to complete works 10,000 C. F. P. S.		2,249,243.61
Main channel extension and Water Power Act		5,463,702.64
Calumet-Sag Channel		555,061.39
Miscellaneous		22,337.19
Administration other than Sanitation, 1890-1913		796,102.11
Maintenance and operation		1,660,024.61
City of Chicago Contract, Oct. 27, 1910		1,688,053.62
Expended by City of Chicago Intercepting sewers, pumping stations, etc., 1880-1907		7,404,162.74
Fixed Charges		10,521,484.26
Grand total		$84,802,748.17

IN THE

District Court of the United States

UNITED STATES OF AMERICA, *Complainant,* vs. THE SANITARY DISTRICT OF CHICAGO, *Defendant,*	C. C. No. 29,019 and Equity No. 114.

INDEX OF EXHIBITS OFFERED IN EVIDENCE BEFORE COMMISSIONERS APPOINTED TO TAKE TESTIMONY IN SAID CAUSE.

Appearances:

Mr. James H. Wilkerson,
United States Attorney, and
Mr. Albert L. Hopkins,
Assistant United States Attorney,
For Complainant.

Mr. Edmund D. Adcock and
Mr. Alfred S. Austrian,
For Respondent.

1914

Chicago

VOL. VII.

CLASSIFIED TABLE OF CONTENTS—EXHIBITS.

Exhibits Attached to Bill of Complaint of the United States, No. 114.

Number	Name	Page
A	War Department Permit, May 8, 1899. Permits 200,000 cubic feet per minute	1
B	War Department Order, April 9, 1901. Orders observance of 1899 permit	2
C	War Department Letter, July 23, 1901. Grants 300,000 cubic feet per minute between hours of 4 p. m. and midnight	3
D	War Department Permit, December 5, 1901. Permits not to exceed 250,000 cubic feet per minute throughout 24 hours	4
E	War Department Permit, January 7, 1903. Permits 350,000 cubic feet per minute till March 31, 1903	5
F	Sanitary District Letter, February 5, 1912. Application for 10,000 C. F. S.	6
G	War Department Letter. Reply to application for 10,000 C. F. S.	7

Exhibits Attached to the Answer of the Sanitary District of Chicago.

A	Copy of Act of May 29, 1899, creating the Sanitary District, and amendments thereto	19
B	Outline map of Chicago River and branches	21
C	War Department Letter, March 14, 1907. Relates to reversal of flow of Calumet River	23
D	War Department Letter, September 11, 1907. Permit to construct north shore channel	26
E	War Department Letter, June 30, 1910. Permit to construct Calumet Sag channel	27
F	Memorial to Congress on the subject of the Illinois and Michigan Canal, Laws, Extra Session, 1826, p. 97	29
G	Ordinance (June 5, 1865) for cleansing Chicago River	31

243 987

Number	Name	Page
H	Sanitary District Letter, June 16, 1896. Application for improvement of Chicago River; also map of Chicago River accompanying same	31
I	War Department Letter, July 3, 1896. Permit for the improvement of Chicago River	37
J	Sanitary District Letter, April 26, 1900. Application for improvement of Chicago River	38
J1	Sanitary District Letter, June 7, 1900. Relative to improvement of Chicago River	39
K1 and K2	Maps of Chicago River, 18th to 31st streets. Sent to Secretary of War, June 7, 1900	41
L	War Department Letter, June 11, 1900. Permit to improve Chicago River	43
L1	War Department Letter, July 11, 1900. Permit to improve Chicago River	44
M	Map of Sanitary District of Chicago, 1913	47

CLASSIFIED TABLE OF CONTENTS—VII EXHIBITS.

Complainant's Exhibits.

Number	Name	Page
1	Discharge Curve—St. Clair River Increment=23,820 C. F. S.	49
2	Discharge Curve—St. Lawrence River Increment=28,870 C. F. S.	51
3	Discharge Curve—Niagara River International Bridge Section Increment=21,900 C. F. S.	53
4	Discharge Curve—Niagara River Open Section Increment=21,640 C. F. S.	55
5	Hydrograph (1860-1912, inclusive). Monthly water levels Lakes Superior, Michigan, Huron, Erie, Ontario	57

Defendant's Exhibits.

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
1	General Chart of Lake Superior	59
2	Chart No. 3, St. Mary's River. Head of Hay Lake to Whitefish Bay	61
3	Chart No. 2, St. Mary's River. Twin Islands to Sault Ste. Marie	63
4	Chart No. 1, St. Mary's River. Lake Huron to Twin Islands	65
5	General Chart of Lake Michigan	67
6	General Chart of Lake Huron	69
7	Chart, St. Clair River, including foot of Lake Huron and St. Clair Flats Canal	71
8	Chart, Lake St. Clair	73
9	Chart of Detroit River	75
10	Chart, Lower Detroit River, showing Livingstone Channel	77
11	Chart, Lake Erie, including the waterways between Lakes Ontario and Huron	79
12	Chart, Buffalo Harbor and Niagara River to the Falls, New York	81
13	Chart, Niagara River from above the Falls to Lake Ontario	83
14	Chart, Lake Ontario	85
15	Chart No. 6, St. Lawrence River	87
16	Chart No. 5, St. Lawrence River	89
17	Chart No. 4, St. Lawrence River	91
18	Chart No. 3, St. Lawrence River	93
19	Chart No. 2, St. Lawrence River	95
20	Chart No. 1, St. Lawrence River	97
21	Seven (7) sheets, containing the U. S. Lake Survey Discharge Measurements of the St. Clair River, Dry Dock Section, 1899, 1900, 1901, 1902, 1908	99-105
22	Six (6) sheets, containing U. S. Lake Survey Records of St. Clair River, as follows	106-111
	Sheet 1. Mean Slope, November-December, 1908	106
	Sheet 2. Summary of 1908 Gorge Section Discharge Measurements	107
	Sheet 3. Summary of 1908 Dry Dock Section Discharge Measurements	108
	Sheet 4. Discharge Measurements, Gorge Section, 1908, 1909	109
	Sheet 5. Same as Sheet 4, 1909	110
	Sheet 6. Discharge Measurements, Dry Dock Section, 1908	111

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

Number	Name
23	Thirty-seven (37) sheets containing U. S. Lake Survey Records of St. Clair River, as follows.....112- Sheets 1-9, incl., Daily Mean Water Surface Elevations .....11 Sheet 10. Observation on Time of Travel of Wave. Sheets 11-14. Discharge Measurements George Section, 1910 .....12 Sheet 15. Discharge Measurements Dry Dock Section, 1910 ..... Sheets 16-22. Summary Discharge Measurements. Delta Section .....12 Sheets 23-25. Sketches showing location of Sections and Gages on St. Clair River.....13 Sheet 26. Curves of Local Slope Head of River.... Sheet 27. Discharge Curve St. Clair River. Increment = 35,145 ..... Sheets 28-31. Current Velocity curves showing effect of passing vessels.....13 Sheets 32-37. Cross Sections. Delta Sections....14
24	Five (5) sheets containing summary of discharges of Niagara River, 1898, 1899, 1900.....14
25	Two (2) sheets containing summary of discharges of St. Lawrence River, 1900, 1901.....154-155
26	Six (6) tables giving Monthly Mean Elevations of Water Surface of Lakes Superior, Michigan, Huron, St. Clair, Erie and Ontario, 1860-1913 inclusive.....156-16
27	Three (3) tables giving Monthly Mean Elevations of Water Surface, as follows.....168-170 Table 1. Detroit River at Amherstburg, Ont. Table 2. Lake St. Clair at Windmill Point. Table 3. Detroit River at Fort Wayne.
28	Eight (8) sheets of Daily Mean Elevations of Water Surface, Lakes St. Clair and Huron, during periods of discharge measurements 171-17
29	Nineteen (19) sheets of Daily Mean Elevations of Water Surface as follows .....181-18 Sheets 1-7 incl.., Amherstburg, Ont., 1898, 1899, 1900, 1909, 1910. Sheets 8-14 incl., Cleveland, Ohio, 1898, 1899, 1900, 1909, 1910. Sheets 15-29 incl., Buffalo, N. Y., 1898, 1899, 1900, 1901, 1902, 1909, 1910.

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
30	Five (5) sheets of Daily and Monthly Mean Elevations of Water Surface, as follows	201-205
	Sheet 1. Miscellaneous Automatic Gage Records.	
	Sheets 2-3 incl. Daily, Oswego Records, 1900, 1901.	
	Sheets 4-5 incl. Daily, Ogdensburg Records, 1900, 1901.	
31	Seven (7) tables giving the mean monthly and annual rainfall on Lakes Superior, Michigan, Huron, Erie and Ontario, 1895-1906	206-210
32	Pages 2855-2883, Appendix FFF 2, Annual Report Chief of Engineers for 1903, being the Report of E. S. Wheeler upon Outflow, Rainfall and Evaporation in the Valley of Great Lakes	211-247
33	Report of the International Waterways Commission on Regulation of Lake Erie, 1910	248-347
34	Consisting of a series of 65 Tables, 6 Charts and 11 Plates based on Williams Exhibits 1 to 33 incl., and 35 in this case, and the Records of United States Lake Survey, Reports of the Chief of Engineers, U. S. A., of the United States Geological Survey and of the United States Weather Bureau; and of Officials of certain States and Municipalities. (For Index See VII, 350-355)	349-547
35	Five (5) Charts of Plottings of Daily Mean Elevation of Water Surface, as follows	548-567
	Chart I. Lakes Huron and St. Clair, 1889, 1900, 1901	548-550
	Chart II. Lakes Huron and St. Clair, 1908, 1909, 1910	550-555
	Chart III. Lake Erie at Cleveland, 1898, 1899, 1900	556-560
	Chart IV. Lake Erie at Buffalo, 1898, 1899, 1900	561-565
	Chart V. Lake Ontario, Ogdensburg and Oswego, 1900, 1901	566-567

FREDERICK P. STEARNS' EXHIBITS FOR DEFENDANT.

1	Seven (7) tables as follows	568-574
	Table A, Local Supply and Storage, Lake Ontario	568
	Table B, Local Supply and Storage, Lakes St. Clair and Erie	569
	Tables C and D, Niagara River Discharge Deduced from St. Lawrence River Discharge	570, 571

FREDERICK P. STEARNS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
	Tables E and F, St. Clair River deduced from Niagara River	572, 573
	Table G, Comparisons of Discharges St. Lawrence and St. Clair Rivers	574
2	Four (4) charts, being plottings of following	575-581
	Chart 1. Stearns Exhibit 1, Table C	575
	Chart 2. Stearns Exhibit 3	577
	Chart 3. Stearns Exhibit 1, Table F	579
	Chart 4. Stearns Exhibit 1, Table E	581
3	Table giving Niagara Discharge deduced from St. Lawrence 1912 Discharge Curve	583

JOHN R. FREEMAN'S EXHIBITS FOR DEFENDANT.

1	Studies Relative to Chicago Drainage Canal	585
2	Reproduction of Record of U. S. L. S. Gauge No. 5, for May 17, 1899, at Head of St. Clair River	587
3	Hydrographs of Lakes Huron, St. Clair and Erie and Fall of Detroit and St. Clair Rivers, 1873-1898	588
4	Article of B. F. Groat on Current Meters, Paper No. 1259, Transactions Am. Soc. C. E.	589-654
5	Plotting Illustrating Time Interval between gages on St. Clair River	655
6	Plotting showing change in current velocity following fluctuations in water level	656
7, 8 and 9	Plotting showing pulsations of current at Section Dry Dock	657-659

HENRY C. ADAMS' EXHIBITS FOR DEFENDANT.

1	Chicago Death Rates—All causes, 1887-1912	661
2	Plotting of Chicago Death Rates, 1860-1912	662
3	Table comprising death rates—Impure air diseases and impure water diseases, 1887-1912	663
4	Distribution of deaths from Typhoid by sex and age	664
5	Decrease in death rates since opening of Drainage Canal	665
6	Map of Manufacturing Zone of Chicago	666
7 & 8	Federal Forms for reporting boat record	667, 668
9	Plotting of prices of pig iron and rails in Pennsylvania, 1895-1911	669
10	Comparison average monthly prices heavy steel rails in England and United States, 1895-1911	671
11	Plotting average prices light and heavy steel, 1895-1911	673
12	Plotting average prices iron and steel, 1895-1911	675
13	Summary Table of loss that would be sustained by Chicago were present facilities for pure water impaired or destroyed	677

Number	Name	Page
	GEORGE W. FULLER'S EXHIBITS FOR DEFENDANT.	
1	Map of Sanitary District Boundary and the corporate limits of Chicago	679
	KENNETH B. TURNER'S EXHIBITS FOR DEFENDANT.	
1	Vertical Velocity Curves, St. Mary's River	681
	ERNEST W. SCHODER'S EXHIBITS FOR DEFENDANT.	
1	Photograph of Haskell Current Meter	683
2-12 (incl.)	Photographs of Cornell University Canal	684-694
13	Table of Discharge Measurements by Haskell Current Meter in Cornell University Hydraulic Laboratory	695
	GEORGE M. WISNER'S EXHIBITS FOR DEFENDANT.	
1	Map showing the limits of the Sanitary District of Chicago.	697
2	Map showing parts of Cook, Will and DuPage Counties and the Sanitary District	699
3	Chart showing saving to community by reduction of Typhoid Fever since opening of Drainage Canal	701
4	Plotting of Typhoid Fever Death Rates at Chicago, East Chicago, Hammond and Whiting	703
6	Hydrograph average monthly elevation water surface Lake Michigan, 1889-1899 and 1900-1910	705
	Complainant's Exhibits in Rebuttal.	
	WALDEMAR S. RICHMOND'S EXHIBITS FOR COMPLAINANT.	
1	Report of W. S. Richmond on Discharge of Niagara River at Split Section	707-709
2	Still Water Rating Curves of U. S. Lake Survey Current Meters	711
3	Niagara Discharge Plotted against Buffalo Gage	713
4	Cross Sections Wickwire and Oakfield and Transverse Velocity Curves	715
	SHERMAN MOORE'S EXHIBITS FOR COMPLAINANT.	
1-4 (incl.)	Discharge Measurements Chicago Drainage Canal, Lemont, Illinois, Feb. 5, 1914	717-720
5	Mean 24 hour Curve of Flow, Chicago Drainage Canal, Lemont, Ill.	721
	FRANCIS C. SHENEHON'S EXHIBITS FOR COMPLAINANT.	
A	Plotting of Discharge Measurements and lines for increments 34,000 and 21,600 C. F. S.	723

FRANCIS C. SHENEHON'S EXHIBITS FOR COMPLAINANT.

Number	Name	Page
B	Plotting of Increment of Niagara—21,900 C. F. S. (Bridge Section), and lines showing departure of one, two and three per cent	725
C	Plotting of 30 Measurements of Niagara River (Bridge Section), used by G. S. Williams, also winter measurements included by mistake	727
D	Same as B, only using Open Section Measurements and Increment = 21,640 C. F. S.	729
D-1	Plotting of 89 Measurements of Niagara River (Open Section, used by G. S. Williams	731
E	Plotting Equations of Discharge Suspension Bridge and Whirlpool	733
F	Plotting of Discharge Curve of Niagara River Suspension Bridge Gage	735
G	Plotting of Discharge Curve of Niagara River Whirlpool Gage	737
H	Plotting of Relative Fluctuations of Whirlpool and Gorge Pool Gages	739
I	Plotting of Relative Fluctuations of Water Surfaces, Lakes Huron and St. Clair	741
J	Plotting of Relative Fluctuations of Water Surfaces, Lakes Erie and Ontario before and after Gut Dam	743
K	Three Curve Series—Sheet 1—Water Level and Discharge Curves, Lake Erie and Niagara River	745
L	Three Curve Series—Sheet 2	747
M	Three Curve Series—Sheet 3	749
N	Three Curve Series—Sheet 4	751
O	One Curve Series—Sheet 1—Water Level and Discharge Curves, Lake Erie and Niagara River	753
P	One Curve Series—Sheet 2	755
Q	One Curve Series—Sheet 3	757
R	Curves showing observed and computed Elevations, Lakes Michigan, Huron, Erie, Ontario (also Complainant's Exhibit "A")	759
S	Discharge Curve St. Lawrence River, Sherman Moore, 1912	761
T	Comparison of St. Lawrence (1912), Discharge with Niagara Discharge, Complainant's Equation	763
U1 U2 U3 U4 U5	A series of sheets of computations establishing the Increment of the Niagara River	765-769
V	Curves showing observed and computed Elevations of Niagara River by Chippawa Gage	771

Defendant's Exhibits in Surrebuttal.

George M. Wisner's Exhibits for Defendant.

Number	Name	Page
7, 8, 9, 10, 11	Five (5) maps of the Chicago River from Lake Michigan through the main branch and south and west on the south branch to Ashland Avenue	733-781
12	Outline of Docks along Chicago River from 18th Street to Pennsylvania Railroad, prior to improvements	783
13	Same as Wisner Exhibit 12—Subsequent to improvement	785
14A	Curves of Flow at Power House and Controlling Works during Test of February 22 and 23, 1914	787
14B	Curves of Flow at Power House, Lemont, Summit and Dearborn Streets, Feb. 22, 23, 1914	788
14C	Water Levels in Main Channel and Chicago River, Feb. 22, 23, 1914	789

George M. Wisner's Exhibits for Defendant.

14D, E, & F.	Correspond to 14A, 14B and 14C for Test of March 8 and 9, 1914	790-792

Gardner S. Williams' Exhibits for Defendant.

36	Direction Measurements of Vertical Curves, International Bridge, Niagara River	793
37	Field Data on Vertical Curve, Span 6, Station 4/12 International Bridge	796
38	Plotting Vertical Curves, Niagara River, Sectional Oakfield, Vertical 8	797
39A, B	Plotting Hourly Water Levels, Buffalo and Chippawa, Nov., 1906	799, 801
39C, D	Table of Direction Measurements on Vertical Curves, Niagara River	802-805
39E1, E2, E3, E4	Plotting Buffalo Gage, Computed from Chippawa	807-813
40	Diagram giving analysis of method used for locating Direction Meter A, at tenths of depth	815
41	Discharge Measurements (Records), Niagara River (1907-1908)	817-821
42	Hourly Water Levels, Nov., 1906 (Table), Buffalo and Chippawa	822-829

SPECIAL CROSS INDEX OF U. S. EXHIBITS.

Page of printed record	Page of folio of exhibits	Description used in text of testimony	Description used in folio of exhibits	Page introduced	Remarks
7	49	Ex. 1, Feb. 15, '09	U. S. Ex. No. 1	7	Lowering Michigan-Huron

EXHIBITS ATTACHED TO BILL OF COMPLAINT OF THE UNITED STATES NO. 115, EXHIBITS A TO G INCLUSIVE.

EXHIBIT "A."

"WHEREAS, by Section 10 of an act of Congress approved March 3, 1899, entitled 'An Act making appropriations for the construction, repair and preservation of certain public works, on rivers and harbors, and for other purposes,' it is provided that it shall not be lawful to alter or modify the course, location, condition or capacity of the channel of any navigable water of the United States unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same:

AND WHEREAS, The Sanitary District of Chicago, a municipal corporation, organized under the laws of the State of Illinois, has constructed an artificial channel from Robey street, Chicago, to Lockport, and has been heretofore granted permission by the Secretary of War to make certain improvements in the Chicago river for the purpose of correcting and regulating the cross section of the river so as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles an hour, it being intended to connect the said artificial channel with the west fork of the south branch of Chicago river at Robey street in the said City of Chicago.

AND WHEREAS, The said Sanitary District of Chicago has now applied to the Secretary of War for permission to divert the waters of the said Chicago river and cause them to flow into the said artificial channel at Robey street as aforesaid;

AND WHEREAS, The said Sanitary District of Chicago represents that such movable dams and sluice gates as are necessary to, at all times, secure absolute and complete control of the volume and velocity of flow through the Chicago river have been constructed;

NOW THEREFORE, The Chief of Engineers having consented thereto, this is to certify that the Secretary of War hereby gives permission to the said Sanitary District of Chicago

to open the channel constructed and cause the water of Chicago river to flow into the same, subject to the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it become apparent that the current created by such drainage works in the south and main branches of Chicago river, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago river and its South Branch.

3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago river.

Witness my hand this 8th day of May, 1899.

R. A. ALGER,
Secretary of War."

(WAR SEAL OFFICE)
JOHN M. WILSON,
Brig. Genl. Chf. of Engrs. U. S. A.

EXHIBIT "B".

"WHEREAS, under date of May 8th, 1899, the Secretary of War granted permission unto The Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of Chicago river to flow into the same, upon the following condition, *inter alia:*

'2—That if, at any time, it becomes apparent that the current created by such drainage works in the south and Main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south Branch.'

AND WHEREAS, It is alleged by various commercial and

navigation interests that the present discharge from the river into the Drainage Canal sometimes exceeds three hundred thousand (300,000) cubic feet per minute, causing a velocity of nearly three (3) miles per hour, which greatly endangers navigation, in the present condition of the river.

Now, THEREFORE, This is to certify that the Secretary of War, upon the recommendation of the Chief of Engineers, hereby directs said Sanitary District to regulate the discharge from the river into the Drainage Canal so that the maximum flow through the Chicago river and its south branch shall not exceed two hundred thousand (200,000) cubic feet per minute.

WITNESS my hand this ninth day of April, 1901.

ELIHU ROOT,
Secretary of War."

EXHIBIT "C".

"WAR DEPARTMENT,
WASHINGTON,

File No. 2560 of 1900.

July 23, 1901.

SIR:

Referring to War Department order of April 9th last, restricting the flow of water through the Chicago River under War Department permit of May 8, 1899 to 200,000 cubic feet per minute, and replying to your letter of the 15th instant, in which you request, for reasons stated, that the said order be amended to permit a flow of 300,000 cubic feet per minute between the hours of 4 P. M. and twelve o'clock midnight, I beg to inform you that I have this day approved the modification last referred to, which approval will be subject to revocation by the Department in case the increase shall prove to be dangerous to navigation.

Very respectively,

ELIHU ROOT,
Secretary of War.

Mr. Alexander J. Jones,
President, Sanitary District of Chicago,
Chicago, Illinois."

EXHIBIT "D".

"J. A. G. O.
(6353).

WHEREAS, Under date of May 8th, 1899, the Secretary of War granted permission unto the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of Chicago River to flow into the same, upon the following condition, *inter alia;*

"2.—That if, at any time, it becomes apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch";

AND WHEREAS, The Secretary of War subsequently directed said Sanitary District of Chicago, to regulate the discharge of water into the Chicago Drainage Canal so that the maximum flow through the Chicago River shall not exceed 200,000 cubic feet per minute from midnight to 4 p. m., nor 300,000 cubic feet per minute from 4 p. m. to midnight;

AND WHEREAS, Said Sanitary District of Chicago has applied to the Secretary of War for permission to increase the flow between midnight and 4 p. m. daily, to 250,000 cubic feet per minute; and the Chief of Engineers has recommended that the increase applied for be granted, but that the rate of flow from 4 p. m. to midnight be reduced to 250,000 cubic feet per minute, so that the flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day.

NOW, THEREFORE, This is to certify that, in accordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto the said Sanitary District of Chicago permission to regulate said discharge so that the maximum flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day, upon the following conditions:

1.—That this permission shall be in lieu of the present authorized rates of flow as stated above.

2.—That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

3.—That said Sanitary District of Chicago shall be responsible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

WITNESS my hand this 5th day of December, 1901.

W. CARY SANGER,
Assistant Secretary of War."

EXHIBIT "E".

"J. A. G. O.
(6353)

WHEREAS, under date of December 5, 1901, by an instrument supplementary to the original permission granted by the Secretary of War, May 8, 1899, to the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of the Chicago River to flow into the same, the Secretary of War, pursuant to authority reserved in said permission of May 8, 1899, gave permission to the Sanitary District of Chicago to regulate said discharge so that the maximum flow per minute throughout the twenty-four hours of the day, upon the following conditions, *inter alia:*

"That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require":

AND WHEREAS, The said Sanitary District of Chicago has applied for permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute during the closed season of navigation, in order to carry off the accumulations of sewage deposit which line the shores along the city;

NOW, THEREFORE, This is to certify that, in accordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto said Sanitary District of Chicago permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute, until the 31st day of March, 1903, after which date it shall be reduced to 250,000 cubic feet per minute, as now authorized, upon the following conditions:

1.—That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

2.—That said Sanitary District of Chicago shall be respon-

sible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

WITNESS my hand this seventeenth day of January, 1903.

W. CARY SANGER,
Assistant Secretary of War."

EXHIBIT "F".

"THE SANITARY DISTRICT
OF CHICAGO.
Chicago, February 5th, 1912.

SIR:—

On behalf of the Board of Trustees of The Sanitary District of Chicago, I have the honor to apply for enlargement of the terms of an instrument executed by The Secretary of War May 8, 1899, as modified by instruments similarly executed on December 5, 1901, and June 30, 1910, respectively, in the following particulars and in view of the facts hereinafter set forth, to wit:

The flow of water from Lake Michigan through the canal of The Sanitary District of Chicago is now limited by the said instruments to 4167 cubic feet per second.

The population of the Sanitary District, the sewage of which is to be disposed of through the channels constructed and to be constructed by the said District, exceeds 2,500,000 persons, and is rapidly increasing. The only method at present available for disposing of the sewage of this population is by diluting the same with water withdrawn from Lake Michigan and flowing through the Chicago Drainage Canal. The least amount of water necessary to render sewage innocuous by the dilution method has been estimated by well recognized sanitary experts as 1,000 feet per second for every 300,000 inhabitants; so that the amount permitted to be withdrawn by the instruments to which reference has been made is much below the amount at present needed by the District.

The Sanitary District has been for some time engaged in investigating methods and devising plans for the treatment of the sewage with a view to requiring less water for its safe dilution in the future. The methods of other states and countries for such treatment of sewage, are not as yet entirely satisfactory to all concerned, and any changes of methods for large cities must necessarily require several years.

Until these experiments are concluded and proper works

installed, the use of additional water from Lake Michigan is essential to the health of the large population of the City of Chicago and of the Sanitary District and of those who live adjacent to the Des Plaines and Illinois rivers into which such waters are discharged.

Subject therefore to such restrictions as you may deem proper for the protection of the public interest, and to such a method of supervision as you may suggest to promote the general welfare, and pending the completion of the investigations now being conducted to render the use of increasing quantities of water in the future necessary; I have the honor to apply for permission for The Sanitary District of Chicago to withdraw from Lake Michigan through the Chicago river and Calumet river—not to exceed ten thousand cubic feet of water per second; such permission to be revocable at any time by The Secretary of War, and subject to such action as the Congress of the United States may see fit to take in the premises.

Respectfully submitted,

GEORGE M. WISNER,
Chief Engineer.

HON. HENRY L. STIMSON,
Secretary of War,
Washington, D. C."

EXHIBIT "G."

In the Matter of the Application of the Trustees of The Sanitary District of Chicago for Permission to Divert from Lake Michigan 10,000 *Cubic Feet of Water Per Second.*

WAR DEPARTMENT.

WASHINGTON, January 8, 1913.

The Sanitary District of Chicago applies to the War Department for permission to increase the amount of water it is authorized to withdraw from Lake Michigan from 4,167 cubic feet per second, the amount now authorized, to 10,000 cubic feet per second.

The Chicago Drainage Canal was opened in January, 1900. It reverses the flow of the Chicago River, which formerly emptied into Lake Michigan, and as a result a portion of the waters of that lake, instead of following their former course

through Lakes Huron, Erie and Ontario into the St. Lawrence, are now carried across the watershed into the Illinois River, and through that to the Mississippi and the Gulf of Mexico. The canal thus serves as a system of drainage for the City of Chicago, carrying the sewage of that city southward to the Mississippi, and thus protects the water supply of that city, which is taken from Lake Michigan.

Permission to divert water from Lake Michigan was first granted by my predecessor, Secretary Alger, on May 8, 1899. He permitted a flowage of 5,000 cubic feet per second, but his permit contained the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it becomes apparent that the current created by such drainage works in the south and main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south branch.

Subsequently, during the administration of Secretary Root, the amount of the current permitted to be taken was modified or restricted until December 5, 1901, when it was fixed at the amount now permitted, and these permits contained the condition—

that the permission herein given shall be subject to such modifications as in the opinion of the Secretary of War the public interests may from time to time require.

On March 14, 1907, an application made for permission to divert an additional 4,000 cubic feet per second for the purpose of reversing the current of the Calumet River and flowing that river also through the canal to drain the southern portion of Chicago was denied by Secretary Taft in an opinion in which he referred once more to the desirability of submitting "this question of capital and national importance to the Congress of the United States."

It is clear that even under the conditions heretofore manifested on these applications, the proposition to divert the waters of Lake Michigan into another watershed has not been entertained without hesitation and careful restriction by my predecessors. The propriety of obtaining congressional sanction for the project has been pointed out from the beginning; and the form in which the permit has been granted, even for the moderate amount of diversion permitted, has been so phrased as to indicate that the permission was predicated upon the absence of any substantial injury to commerce.

The sanitary canal has never received the direct sanction of Congress. It was built solely under the authority of the State of Illinois, as given in its 1889 general act for creating sanitary districts. And although pursuant to the suggestion of my predecessors the question of the propriety of its diversion of water from Lake Michigan was presented urgently in the reports of the Chief of Engineers for the years 1899 and 1900 as transmitted to Congress, no action upon the question has ever been taken by that body. In the argument before me it was urged that the present canal represented the growth and development of a national policy expressed in two acts of Congress, 1822 and 1827, which authorized the construction of a canal "to connect the Illinois River with Lake Michigan," thus connecting the two watersheds. (Acts of Mar. 30, 1822, and Mar. 2, 1827.) But these statutes authorized a canal for the purpose of navigation and not sanitation. (*Missouri* v. *Illinois,* 200 U. S., 526.) The Illinois and Michigan Canal, actually constructed under their authority, derived its water for navigation purposes from the Calumet, Des Plaines, and Chicago Rivers, and not from the Lakes. And although in the latter part of its existence it was used to a very slight extent to help purify the waters of the Chicago River and thus sanitate the City of Chicago, such a purpose could not have been dreamed of at the time its construction was authorized by Congress, 90 years ago. I can not see that its authorization and construction offer the slightest congressional sanction for the great canal now under discussion, which was not even contemplated until much more than half a century later. Even at the time when the present canal was constructed and opened it is very evident that its ultimate possible effect upon the navigation of the Great Lakes was not clearly realized by those interested in that navigation. The evidence before me indicates that the withdrawal of water from Lake Michigan at Chicago would require about five years to produce its full effect upon the levels of the Great Lakes (see report of International Waterways Commission on Chicago Drainage Canal, p. 7) and that this effect would be still further obscured by periodic oscillations in the lake levels. These facts may easily explain any inaction on the part of the Nation and their representatives to this withdrawal of water and make it clear that any argument of implied acquiescence must be scrutinized with unusual care.

In this respect the situation is now very different. The present application was opposed by representatives of 23

cities and 6 States interested in harbors and commerce upon the Great Lakes, notably the Cities of Duluth, Milwaukee, Toledo, Cleveland and Buffalo. It was opposed by representatives of the navigation interests engaged on the Chicago River as well as on the Great Lakes; and by the official representatives of the Canadian Government as well as private Canadian interests engaged in the navigation of the Lakes and the St. Lawrence River, including representatives of the Cities of Kingston and Montreal.

A very careful consideration of the voluminous evidence and statements submitted, as well as a consideration of the reports of other commissions and boards of engineers who have investigated the subject, leaves no doubt in my mind that the withdrawal of 10,000 cubic feet per second would substantially interfere with the navigable capacity of the Great Lakes and their connecting rivers. The Chief of Engineers, whose statutory authority in passing upon this application is concurrent with and independent of my own, and whose opinion upon such a question of scientific conclusion must be given especially weight, so states in his recommendation. His conclusions are corroborated by the authority of other boards of investigation, notably the report of the International Waterways Commission of January 4, 1907.

Careful observations and calculations conducted under the offices of the United States Lake Survey and reported through the Chief of Engineers, covering observations for the last 46 years, indicate that a withdrawal of 10,000 cubic feet per second would reduce levels at various places as follows:

	Inches.
Lakes Huron and Michigan	6.9
Lake St. Clair	6.3
Lake Erie	5.4
Lake Ontario	4.5
St. Lawrence River and Rapide Plat	4.8 plus.

The foregoing effects would be produced at mean lake levels; the lowering effects would be much greater at low-water periods—the precise time when any additional shortage would be most keenly felt. This reduction would create substantial injury in all of the American harbors of the Great Lakes and in the St. Marys, St. Clair and Detroit Rivers. It would produce equal injury in Canadian harbors on the Great Lakes, and a still greater injury on the lower St. Lawrence, the

Canadian officials claiming a probable lowering effect of 12 inches at Montreal at low water.

The United States has improved about 106 harbors and rivers on the Great Lakes affected by this diversion and has spent on such improvement over ninety millions of dollars. The Canadian Government has improved over 50 harbors on Georgian Bay and Lakes Huron, St. Clair, Erie and Ontario. By treaty, American vessels are accorded equal rights of navigation with Canadian vessels in all these waters, including the St. Lawrence River. The reduction of the water in these harbors and channels would diminish to just that extent the amounts of these improvements, and would nullify to just that extent the effects of the moneys which have been appropriated for that purpose by the respective Governments. Connecting various portions of these waterways are the two canals at the Sault Ste. Marie, the Welland Canal, and a number of canals on the St. Lawrence River. The available depth of water over one or all sills of each of these canals would be affected, and in some cases reconstruction might even be made necessary.

The enormous lake traffic which uses these harbors and these rivers is increasing with great rapidity, both in gross volume and in the size and average draft of the vessels employed therein. The Chief of Engineers reports that to lower the water surface 6 inches would reduce the permissible load of one of the large modern vessels by from 300 to 550 tons, with a consequent loss of from $3,600 to $7,500 in freights for such vessel per season. The International Waterways Commission reported that it would be a conservative estimate which would make the loss to the navigation interests resulting from a reduction of 6 inches in the depth of water as $1,500,000 per annum, or a sum which, capitalized at 4 per cent., would amount to a loss of $37,500,000 (see third progress report of International Waterways Commission of Dec. 1, 1907, p. 24). The lowest careful estimate of injury to American vessels alone is reported by the Chief of Engineers at $1,000,000 per year.

The argument was made before me that, owing to the well-known fact that the levels of the lake vary, owing to winds and change of barometric pressure, by amounts even greater than the reduction which would be caused by this canal, therefore the proposed reduction is of no consequence. This argument is well disposed of in the report of the International

Waterways Commission of January 4, 1907, on page 8, as follows:

It is evident that the average level of the lake may be lowered considerably without the change becoming immediately apparent, and that fact has been used as an argument to prove that the lowering caused by the Chicago Drainage Canal is of no consequence to those interested in navigation. Since they cannot see it they will not know it and will not feel it. The argument is fallacious. It is true that they cannot see it immediately, but they will soon feel it and will know it through the most costly means of acquiring knowledge—the injury to their material interests. The oscillations will remain the same as before, but low water will fall lower and high water will rise less high. The average draft of vessels must be diminished by the amount that the average level is lowered unless the depth be restored by remedial works.

In a word, every drop of water taken out of Chicago necessarily tends to nullify costly improvements made under direct authority of Congress throughout the Great Lakes, and a withdrawal of the amount now applied for would nullify such expenditures to the amount of many millions of dollars, as well as inflict an even greater loss upon the navigation interests using such waters.

On the other hand, the demand for the diversion of this water at Chicago is based solely upon the needs of that city for sanitation. There is involved in this case no issue of conflicting claims of navigation. The Chief of Engineers reports that so far as the interests of navigation alone are concerned, even if we should evenually construct a deep waterway from the Great Lakes to the Mississippi over the route of the sanitary canal, the maximum amount of water to be diverted from Lake Michigan need actually be not over 1,000 feet per second, or less than a quarter of the amount already being used for sanitary purposes in the canal. This estimate is confirmed by the report of the special board of engineers on the deep waterway from Lockport, Ill., to the mouth of the Illinois River, dated January 23, 1911. It is also confirmed by the practical experience of the great Manchester Ship Canal in England. From the standpoint of navigation alone in such a waterway too great a diversion of water would be a distinct injury rather than a benefit. It would increase the velocity of the current and increase the danger of overflow and damage to adjacent lands.

We have, therefore, presented in this case claims of entirely different characters and jurisdictions—the claim of sanitation on the one side and of navigation on the other; the vital interest of a single community on the one side and the broad interest of the commerce of the nation on the other. The discretion given to the Secretary of War under sections

9 and 10 of the act of 1899 is very broad, but I have very grave doubts as to whether it was intended to authorize him to grant a permit which would inflict a substantial injury upon commerce in order to benefit sanitation. The entire purpose and scope of that legislation was to make him the guardian of the commercial interests of the nation represented in their waterways. And while he sometimes under that statute must decide that the interests of one class of transportation are less important and must yield to the conflicting interests of another class, I have considerable doubt whether it was intended to give him authority to sacrifice substantial interests of navigation to entirely different claims over which he normally has no jurisdiction whatever.

But however that may be, and without resting my decision upon the question of my legal authority, I am quite clear as a matter of discretion that under the facts presented by this case no further diversion of water should be permitted at Chicago without the direct sanction of the Congress of the United States. I do not for one moment minimize the importance of preserving the health of the great City of Chicago; but when a method of doing this is proposed which will materially injure a most important class of the commerce of the nation and which will also seriously affect the interests of a foreign power, it should not be done without the deliberate consideration and authority of the representatives of the entire nation. The growth of Chicago is phenomenal and its representatives are quite unwilling to put any final limit to the demand which may be made upon the waters of Lake Michigan for its sanitation under the system now in use. I have before me the report of 1911 of the president of the sanitary district in which he says:

> I am of the opinion that the presumption that our water supply is to be limited to 10,000 cubic feet per second, or 600,000 cubic feet per minute, is gratuitous and mischievous and should not be voiced by the officials of this district. I believe that we should have the volume requisite to our needs as they appear and are justified.

It is therefore quite conceivable that compliance with their sanitary needs according to this method of sanitation may eventually materially change this great natural watercourse now existing through the Lakes. The weighing of the sanitation and possibly the health of one locality over against the commerce of the rest of the Nation and the consideration of our relations and obligations to Canada in respect to a great international waterway are not matters of mere technical or scientific deduction. They are broad questions of national

policy. They are quite different in character, for example, from the question of fixing the proper location of a pierhead line or the height or width of a drawbridge over a navigable stream—fair samples of the class of questions which come to the Secretary of War for decision under the above mentioned act of 1899. While the researches and opinions of experts in the respective fields are necessary and useful as an assistance toward reaching a fair and proper policy, the final determination of that policy should belong not to an administrative officer but rather to those bodies to whom we are accustomed to entrust the making of our laws and treaties.

In my view of the proper exercise of my discretion in this matter the foregoing considerations are sufficient for a decision of this case. Having reached the conclusion that the proposed diversion of the waters of Lake Michigan would substantially injure the interests of navigation on the Great Lakes which it is my legal duty to protect, it would clearly follow that the present application should be denied.

I have carefully examined, however, the evidence which both sides have introduced bearing upon the sanitary needs of the City of Chicago, and my conclusion is in no way shaken. I am not persuaded that the amount of water applied for is necessary to a proper sanitation of the City of Chicago. The evidence indicates that at bottom the issue comes down to the question of cost. Other adequate systems of sewage disposal are possible and are in use throughout the world. The problem that confronts Chicago is not different in kind but simply larger and more pressing than that which confronts all of the other cities on the Great Lakes, in which nearly 3,000,000 people of this country are living. The urban population of those cities, like that of Chicago, is rapidly increasing, and a method of disposition of their sewage which will not injure the potable character of the water of the Lakes must sooner or later be found for them all. The evidence before me satisfies me that it would be possible in one of several ways to at least so purify the sewage of Chicago as to require very much less water for its dilution than is now required by it in its unpurified condition. A recent report of the engineer of the sanitary commission (Oct. 12, 1911) proposes eventually to use some such method, but proposes to postpone its installation for a number of years to come, relying upon the present more wasteful method in the meanwhile. It is manifest that so long as the city is permitted to increase the amount of water which it may take from

the Lakes, there will be a very strong temptation placed upon it to postpone a more scientific and possibly more expensive method of disposing of its sewage. This is particularly true in view of the fact that by so doing it may still further diminish its expenses by utilizing the water diverted from the Lakes for water power at Lockport. But it must be remembered that for every unit of horsepower realized by this water at Lockport four units of similar horsepower would be produced at Niagara, where the natural conditions are so much more favorable. Without, therefore, going more into detail in a discussion of this question, I feel clear that no such case of necessity has been presented by the evidence before me as would justify the proposed injury to the many varied interests in the great waterways of our lakes and their appurtenant rivers.

It remains only to consider certain special arguments that have been pressed upon me. It has been urged that the levels of the lakes, even if lowered, could be restored by compensating works. To a certain extent that is true. But the very nature of this consideration offers another illustration of the importance of having the whole question passed upon by Congress. Such compensating works can only be constructed by the authority of Congress and at very considerable cost. It is not a matter which is in the hands of the Secretary of War. Permission to divert water which will at one and the same time nullify the effect of past appropriations and make necessary similar expenditures in the future, should be granted only with the express consent of the body in whose hands the making of such appropriations and the authorization of such works rest.

Furthermore, in most cases such compensating works could only be constructed with the joint consent of our neighbor Canada. The United States Government alone would be unable, even if it were willing to spend its own funds, to compensate for the damage done through the lowering of these levels, unless Canada were willing to join in constructing the portion of such works which would necessarily stand upon Canadian soil.

The question therefore becomes not merely national but international, and this leads me to the consideration of the arguments which were urged by both sides in reference to the treaty with Great Britain in respect to Canada of January 11, 1909. A careful consideration of that treaty fails to indicate to me that it is in any way controlling upon the

questions now before me. It gives to the citizens of both countries certain mutual rights of navigation in the waters of the Great Lakes and their connecting rivers; but beyond that the question of the right to this diversion at Chicago seems to me to have been carefully excluded. The applicants for the permit have urged upon me that article 8 of the treaty gives a preference to the uses of water of the lakes for domestic and sanitary purposes over the uses of such water for navigation. Article 8, however, applies only to future cases brought before the International Joint Commission; and furthermore I am clearly of the opinion that the domestic and sanitary purposes referred to in that article were intended to be the "ordinary" uses of such waters for domestic and sanitary purposes referred to in article 3. It would be quite contrary to our own national policy to give such a preference to an extraordinary sanitary use of such a character as to create a substantial injury to navigation. The matter has been before our own Supreme Court in the case *of the United States* v. *the Rio Grande Dam & Irrigation Co.* (174 U. S., 690). In that case the Supreme Court held that a company which proposed to take the water of the Rio Grande river for the purpose, among others, "of supplying water to cities and towns for domestic and municipal purposes" could be prevented from so doing when the result would be a substantial injury to the navigability of the Rio Grande river farther down. In its opinion the court said:

> The question always is one of fact, whether such appropriation substantially interferes with the navigable capacity within the limits where navigation is a recognized fact. In the course of the argument, this suggestion was made, and it seems to us not unworthy of note, as illustrating this thought. The Hudson river runs within the limits of the State of New York. It is a navigable stream and a part of the navigable waters of the United States, so far at least as from Albany southward. One of the streams which flows into it and contributes to the volume of its waters is the Croton river, a non-navigable stream. Its waters are taken by the State of New York for domestic uses in the City of New York. Unquestionably the State of New York has a right to appropriate its waters, and the United States may not question such appropriation, unless thereby the navigability of the Hudson be disturbed. On the other hand, if the State of New York should, even at a place above the limits of navigability, by appropriation for any domestic purposes, diminish the volume of waters, which, flowing into the Hudson, make it a navigable stream, to such an extent as to destroy its navigability, undoubtedly the jurisdiction of the National Government would arise and its power to restrain such appropriation be unquestioned; and within the purview of this section (act of Sept. 19, 1890, ch. 907) it would become the right of the Attorney General to institute proceedings to restrain such appropriation.

The treaty, however, contains provisions in its article 10 by which "any questions or matters of difference arising between the high contracting parties involving the rights, obli-

gations, or interests of the United States or of the Dominion of Canada, either in relation to each other or to their respective inhabitants, may be referred for decision" to an international joint commission established by the said treaty. The hearing before me brought forth the fact that the Government of Canada regards the proposal contained in this application as one which effects the material interests of that country. The establishment by formal treaty between the two countries of a tribunal with jurisdiction to decide just such questions seems to me to afford an additional reason against the assumption of jurisdiction to decide the question by an administrative officer of one of those countries.

In short, after a careful consideration of all the facts presented, I have reached the following conclusions:

First. That the diversion of 10,000 cubic feet per second from Lake Michigan, as applied for in this petition, would substantially interfere with the navigable capacity of the navigable waters in the Great Lakes and their connecting rivers.

Second. That that being so, it would not be appropriate for me, without express congressional sanction, to permit such a diversion, however clearly demanded by the local interests of the sanitation of Chicago.

Third. That on the facts here presented no such case of local permanent necessity is made evident.

Fourth. That the provisions of the Canadian treaty for a settlement by joint commission of "questions or matters of difference" between the United States and Canada offer a further reason why no administrative officer should authorize a further diversion of water, manifestly so injurious to Canada, against Canadian protest.

The prayer of the petition is therefore denied.

HENRY L. STIMSON,
Secretary of War.

War Department
Washington,

March 14, 1907.

In the matter of the application of the Sanitary District of Chicago to reverse the flow of the Calumet River.

This application is made under Section 10 of the act of March 3, 1899 (30 Stat. L., 1151), which provides as follows:

> "Sec. 10. That the creation of any obstruction, not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is hereby prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty or other structures in any port, roadstead, haven, harbor, canal, navigable river, or other water of the United States, outside established harbor lines, or where no harbor lines have been established, except on plans recommended by the Chief of Engineers and authorized by the Secretary of War; and it shall not be lawful to excavate or fill or in any manner to alter or modify the course, location, condition, or capacity of, any port, roadstead haven, harbor, canal, lake, harbor of refuge. or inclosure within the limits of any breakwater, or of the channel of any navigable water of the United States, unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same."

The application of the Sanitary District is for leave to reverse the flow in the Calumet River in such a way as to make the water to flow out of the lake instead of to flow into it and to discharge the water from the Calumet River into the Drainage Canal. The Chief of Engineers was at first of opinion that such a change in the flow of the river, it was not within the power of the Chief of Engineers to recommend, or within the power of the Secretary of War to permit. This expression of opinion as to the construction of the statute was submitted to the Judge Advocate General, who holds that Section 10, as quoted above, applies to this case and that it is one in which work could be allowed under the recommendation of the Chief of Engineers and the permission of the Secretary of War. Upon the construction of the Judge Advocate General I requested the Chief of Engineers to make his recommendation, which he has done as follows:

February 23, 1907.

1. Respectfully returned to the Secretary of War.

2. The subject of the abstraction of water from Lake Michigan has been elaborately investigated by the Lake Survey Office at Detroit, and the results are published in the annual reports of the Chief of Engineers for the years 1900, 1902 and 1904. The international Waterways Commission has also given it careful consideration, and its conclusions are set forth in report of January 4, 1907, printed as War Department Document No. 293.

3. In my opinion, this abstraction will undoubtedly lower the levels of all the waters of the Great Lakes, except those of Lake Superior, and thus diminish the navigable capacity and depth of the various channels and harbors which have been deepened and improved under authority of Congress.

4. Leaving out Lake Superior, there are more than 100 works of river and harbor improvements on the Great Lakes and their connecting waters, for which appropriations aggregating more than $80,000,000 have been made. The application of this vast sum has resulted in securing and maintaining specified depths and widths of channel, which Congress has decided to be required for the accommodation of the traffic using those waters.

5. To diminish these depths, even to a slight extent, would not only prove a serious injury to the traffic, but would practically undo the work which has been accomplished by Congressional direction, and necessitate the expenditure of further large sums of money for restoration. Any project that tends, in a measure, to annul or reverse the orders of Congress, as expressed in the various river and harbor acts appropriating funds for improving the harbors and channels connecting with the Great Lakes, should meet the disfavor of the Department, unless it has been sanctioned by that body. In my judgment, such a project is the one under consideration, and for this reason I am unwilling to recommend favorable action thereon, assuming that the Department is empowered to take such action, as is held by the Judge Advocate General.

A. MACKENZIE,
Brig. Gen., Chief of Engineers, U. S. Army."

It is quite evident from the reading of the statute that Congress intended in this statute, as in many others, to give the

Chief of Engineers authority, independent of the Secretary of War, in reaching a conclusion as to the wisdom and propriety of granting a permit under the section, and that unless the Chief of Engineers shall recommend the granting of the permit, the Secretary of War is without power to give the requested authority. It follows, therefore, that the application must be denied whatever my view of the case.

The decision of the Chief of Engineers and its final character has made it unnecessary for me to consider the merits of the question, but I may say this much, that the application for a change in the Calumet River is to be made the basis for the withdrawal of a large amount of water from Lake Michigan and that all interested in the enormous lake traffic view the settlement of the question with grave apprehension. Added to this, is the international complication which is likely to arise in the threatened lowering of the lake level in the ports and harbors and canals of Canada. On the other hand, it is maintained with great emphasis and elaboration of detail that the change in the Calumet River, is essential to the healthful sanitation of Chicago, and that the threatened injury to navigation is so small as to be negligible.

Between two such great interests, the decision must be affected more or less by large public policy and expediency, and while I agree in the construction of the Judge Advocate General that the issue is left by statutes to the recommendation of the Chief of Engineers and the concurrent decision of the Secretary of War, it may be fortunate that circumstances now require submission of this question of capital and national importance to the Congress of the United States.

WM. H. TAFT,
Secretary of War.

"WAR DEPARTMENT
WASHINGTON, September 11, 1907.

SIR:

Referring to your letter of 2nd instant, in which you request approval of proposed drainage channel to connect Lake Michigan at Wilmette, Ill., with the North Branch of the Chicago River; also permission to construct a pile crib in Lake Michigan at mouth of same, and to deposit filling within the limits of such crib, I beg to inform you that the War Department will interpose no objection to the project as set forth in your letter and indicated on drawing submitted, provided the following conditions are complied with:

1. That the pier constructions, the filling behind the same, and the excavation of the proposed channel shall be done subject to the supervision and approval of the local officer of the Corps of Engineers, U. S. Army, at Chicago, so far as to see that the work authorized is not exceeded;

2. That the total diversion of water from Lake Michigan through the Chicago River into the Illinois River shall be no greater than already authorized by past War department permits;

3. That the work shall be commenced before December 31, 1908, and completed within five years thereafter.

Very respectfully,

ROBERT SHAW OLIVER,
Acting Secretary of War

G. M. Wisner, Esq.,
Chief Engineer, The
Sanitary District of Chicago
American Trust Building,
Chicago, Illinois."

EXHIBIT E.

Permit

WAR DEPARTMENT, WASHINGTON,
June 30, 1910.

SIR:

Referring to your application of the 27th instant on behalf of the Board of Trustees of The Sanitary District of Chicago to open a channel from the Calumet River to its existing Main Channel so as to substitute two routes instead of one between Lake Michigan and its canal, I have the honor to advise you to the following effect:

It appears from the records of the Department that by an instrument executed May 8, 1899, The Sanitary District of Chicago was given permission to connect its Drainage Canal with the South Branch of the Chicago River at Robey Street, in the City of Chicago, and to divert the waters of Lake Michigan through the Chicago River into said canal, subject to certain specified conditions designed to limit the amount of such diversion and in other ways to protect the public interest. The permission so granted was subsequently modified at various times, and by an instrument executed December 5, 1901, the amount of flow was fixed at not exceeding 250,000 cubic feet per minute, equivalent to 4,167 cubic feet per second, which is the present rate allowed. At the time the original permit was given a connection with the Calumet River was not mentioned but if it had been it is probable that a connection with that river as well as with the Chicago River would have been allowed.

So long as the water-flow remains unchanged there seems to be no special objections to its extension to both rivers instead of confining it to a single one, especially since if the new (Calumet) route be developed later to a navigable state the double route will be advantageous to navigation interests. Accordingly, in view of the favorable recommendation of the Chief of Engineers and of the consent thereto by the Attorney General, under the condition hereinafter prescribed, the Department hereby modifies the existing permission so as to allow the division of the already permitted water-flow in such manner as to reach the Sanitary District Canal by way of the Calumet River and a connecting channel, as well as by way of its present route through the Chicago River, subject to all pertinent conditions of the existing permissions and to other express conditions, as follows:

(a) That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of The Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

(b) That if at any time it become apparent that the current created by such drainage work in the Calumet, as well as Chicago rivers, be unreasonably obstructive to navigation, or injurious to property, the Secretary of War reserves the right to close the discharge through said channel or rivers, or to modify it to such an extent as may be demanded by navigation and property interests along said rivers.

(c) That The Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in the Calumet as well as Chicago river.

(d) That the amount of water withdrawn from Lake Michigan, through the Chicago and Calumet rivers together, shall not exceed the total amount of 250,000 cubic feet per minute (4,167 cubic feet per second) already authorized to be withdrawn through the Chicago River alone.

(e) That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

(f) That this permission shall in nowise affect or in any manner be used in the friendly suit now pending in the Circuit Court of the United States for the Northern District of Illinois brought by the United States of America against the Sanitary District of Chicago, to determine the right of the said Sanitary District to divert from Lake Michigan for sanitary purposes an amount of water in excess of that now being diverted, without having first obtained a permit from the Secretary of War.

(g) That the War Department shall have free access at all times to the waterflow records of The Sanitary District of Chicago and free access also to the regulating works and all other parts of its canals for the purpose of checking records or making water-flow measurements.

(h) That the plans for the proposed work shall be submitted to and approved by the Chief of Engineers and the Secretary of War.

(i) That the work shall be subject to the supervision and

approval of the Engineers Officer of the United States Army in charge of the locality.

Very respectfully,

ROBERT SHAW OLIVER,
Acting Secretary of War.

Mr. George M. Wisner,
Chief Engineer, Sanitary District of Chicago, Chicago, Ill.

EXHIBIT "F."

MEMORIAL TO CONGRESS ON THE SUBJECT OF THE ILLINOIS AND MICHIGAN CANAL.

(Laws Extra Session, 1826, p. 97.)

To the Honorable the Senate and House of Representatives of the United States of America in Congress assembled: The memorial of the General Assembly of the State of Illinois respectfully represents that the construction of a canal uniting the waters of Lake Michigan with the Illinois river, will form an important addition to the connecting links in the chain of internal navigation, which will effectually secure the indissoluble union of the confederate members of this great and powerful Republic. By the completion of this great and valuable work, the connection between the north and the south, the east and the west, would be strengthened by the ties of commercial intercourse and social neighborhood, and the union of the states might bid defiance to internal commotion, sectional jealousy and foreign invasion. All the states of the Union would then feel the most powerful motives to resist every attempt at dissolution. To effect so great and desirable an object, your memorialists believe to be of sufficient importance to engage the attention and awaken the munificient patronage of a government whose principle of action is the promotion of the general welfare. Your memorialists are sensibly alive to the spirit of improvement that manifests itself in almost every section of our extensive country, and would fain lend a helping hand in so great and good a cause; their situation, however, forbids their doing much, without the aid of the federal government; into whose treasury almost all the funds whether brought hither by emigrants or earned by the industry of their citizens, are

paid for the purchase of the public lands. While this state of things shall continue and the money thus paid into the treasury of the Union is taken out of our State, our people will not be able to engage in the glorious work of improving our common country. Ought the people of this State to stand by with folded arms and behold the great work of internal improvement progress in other states without making an effort to improve their own conditions, and at the same time advance the interest of our beloved country? A condition thus paralyzed, is at war, not only with our interests, but with the best feelings of our hearts. Did this State possess the public domain lying within its bounds, as in the case with the older members of this confederacy, your memorialists would not appear before your honorable body to solicit aid in this important work. If, as your memorialists believe, the construction of this canal would be highly beneficial to the Union at large; if the receipts into the treasury of the United States would be augmented by the increased sales of public lands; and if the interest of this State would be also advanced thereby; is it unreasonable to apply to a paternal government for assistance in the promotion of such beneficial ends? It is unnecessary for your memorialists to enlarge on the great advantages of this canal to the Union, in the facilities to be afforded in the event of a war with either the Indian tribes inhabiting our frontier, or the British nation. Your honorable body is aware that this State is situated on the borders of an Indian country, filled with numerous and powerful tribes of the sons of the forest. If our country should be again engaged in war, the saving of expense in the transportation of munitions of war, would alone defray the expense of the contemplated canal, and justify the United States in making a liberal appropriation for its construction. Your memorialists do not, however, ask your honorable body to appropriate money out of the treasury to aid them in this work; they only ask for a tract of land, through which the contemplated canal may pass, and which, for a series of years, will be wholly unproductive to the government unless the canal shall be commenced under auspices favorable to its completion; in which event all the land in the vicinity would immediately become available to the United States. Your memorialists sincerely believe that a liberal appropriation of land for this object, would, even in a pecuniary point of view be of immense importance to the treasury of the Union. The public lands in the vicinity would not only sell, but at a considerable advance upon the minimum price. Should this

opinion be correct (and does not experience justify it?) the United States would be gainers by the proposed donation to the State. Your memorialists further state that at their last session, they passed an act of incorporation, upon very liberal terms, authorizing a company to construct the projected canal; but the remoteness of the country from the residence of capitalists, has prevented them from engaging in the work. At their present session, your memorialists have repealed the charter; and their only hope of soon beginning the work depends upon the liberality of your honorable body. Your memorialists have caused the route to be explored and estimates to be made of the probable expense of the work; from which it appears that the cost of constructing the canal will not be less than $600,000 and may possibly amount to $700,000. To the end, therefore, that your memorialists may be enabled to commence and complete this great and useful work, we pray your honorable body to grant to this State the respective townships of land through which the contemplated canal may pass; the avails of which, to be appropriated exclusively, to the construction of said canal, upon such terms and conditions as to your honorable body may seem proper.

EXHIBIT "G."

"An Ordinance for Cleansing the Chicago River and Appropriating the Proceeds of Two Hundred and Fifty Bonds Therefor.

SECTION 1. Be it ordained by the Common Council of the City of Chicago (June 5, 1865), That the plan of the board of public works for cleansing the Chicago River and its branches by cutting down the summit of the Illinois and Michigan Canal below the level of Lake Michigan so as to draw from it at a low stage of water in the lake not less than twenty-four thousand (24,000) cubic feet of water per minute, is hereby approved, and said board are hereby authorized to execute said work.

SECTION 2. That the board of public works are hereby authorized and empowered for the purpose of prosecuting the work described in the previous section, to make any contract necessary to carry into effect such purpose with the trustees of the Illinois and Michigan Canal, in conformity with and subject to the general provisions of the city charter.

SECTION 3. That as a temporary expedient for cleansing the South Branch of the Chicago River, the said board are hereby authorized and empowered to contract with the said trustees for the pumping from the river

into the canal, by the hydraulic works at Bridgeport, and discharging through the canal of such amount of water as shall be found necessary and practicable for such purpose.

SECTION 4. That for the purpose of carrying out the improvement specified in the foregoing sections, the board of public works be and they are hereby authorized to issue 250 bonds of the denomination of $1,000 each, to be dated July 1, 1865, and payable in New York, twenty-five years after the date thereof, with coupons for interest, at the rate of seven per centum per annum, payable semi-annually in New York; the said bonds to be issued in conformity with the provisions of an act of the General Assembly of the State of Illinois, approved February 15, 1865, and entitled 'An act to amend an act entitled an act to reduce the charter of the City of Chicago, and the several acts amendatory thereof, into one act, and to revise the same,' approved February 13, 1863."

EXHIBIT H.

APPLICATION OF THE SANITARY DISTRICT FOR THE IMPROVEMENT OF THE CHICAGO RIVER.

CHICAGO, June 16, 1896.

To the Honorable Daniel S. Lamont,
Secretary of War,
Washington, D. C.

DEAR SIR:

The work of The Sanitary District of Chicago has progressed so far that it is now necessary for us to enter upon that which must be done in the Chicago River to make available the artificial channel which we have under construction from Robey Street, Chicago, to Lockport in Will County, twenty-eight miles distant.

Our connection with Lake Michigan must be through the Chicago river with the West Fork of the South Branch of which we make a junction at Robey Street. We send herewith a map showing in a general way our plans for improving the Chicago River by widening and deepening at the points indicated thereon by red hatchings and by figures which refer to explanation, given in the legend on the map. It is desired to so correct and regularize the cross section of the

river as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles per hour. The cross section necessary to accomplish this can be obtained throughout the greater part of the distance between Monroe Street and Robey Street, by dredging the river to a depth of 20 ft. at mid stream, with 12 ft. at dock lines and a uniform slope away from docks of one foot in five, so that the full depth would be reached forty feet from the dock lines; but there are places so narrow that this cross section can only be obtained by widening the river; and again the depth to be obtained in the vicinity of Van Buren Street is limited by the height of the crown of the tunnel. To obviate this difficulty it is purposed to secure the requisite cross section by constructing a by-pass to the west of the bridges at Adams, Jackson and Van Buren Streets, as indicated. We ask your permission to proceed with the work upon the lines indicated and so far as is consistent with propriety the co-operation of the United States Engineering Department.

Awaiting your favorable reply, and holding ourselves ready to respond to any call from you for fuller information as to our plans, I am

Yours respectfully,

(Signed) B. A. ECKHART,

President.

A copy of the above letter is found at Page 297 of the Clerk's Copy Letter Book "C," being letter book from September 20, 1895, to January 11, 1907.

PERMIT FOR THE IMPROVEMENT OF THE CHICAGO RIVER.

(Permit of July 3rd, 1896.)

Improvement of the Chicago river.

July 3, 1896.

SIR:

I have the honor to acknowledge the receipt of your letter of the 16th ultimo, requesting permission to make certain changes in the capacity of the channel of the Chicago River for drainage purposes at points indicated on the map accompanying the application, and in reply beg to say that upon investigation it is found that the permission requested can be granted upon the following conditions:

1. That while the general plan is approved, the Sanitary District of Chicago must furnish plans in triplicate on an enlarged scale showing each proposed new bridge, each by-pass and each new dock or wharf proposed to be built, in order that the Secretary of War may act intelligently in each case.
2. That this authority shall not be interpreted as approval of the plans of the Sanitary District of Chicago to introduce a current into Chicago River. This latter proposition must hereafter be submitted for consideration.
3. That it will not cover obstructions to navigation by reason of this work while in progress or when completed.
4. That the United States shall not be put to expense by reason of this work.
5. That this authority will expire by limitation in two years from date unless extended.

Very respectfully,

(Signed) JOSEPH B. DOE,
Acting Secretary of War.

B. A. Eckhart, Esq.,
President the Sanitary District of Chicago, Rialto Building, Chicago, Ill.

EXHIBIT J.

THE SANITARY DISTRICT OF CHICAGO.

Security Building.

CHICAGO, April 26, 1900.

To the Honorable
The Secretary of War.

SIR:

The Sanitary District of Chicago, a municipal corporation organized and existing under the laws of the State of Illinois, respectfully represents that, by the laws of the State of Illinois and the charter of this petitioner, it is authorized to enter upon, widen, deepen and otherwise improve any navigable stream, river or other water-way. That in pursuance of the power conferred upon it by the statutes of the State of Illinois, and in the performance of the duties enjoined upon it by the act of the Legislature authorizing its creation, and under which it is acting, it has been determined to improve the Chicago River by widening and deepening the same and to the end that such action on the part of your petitioner may be conformable to law and the statutes of the United States in that behalf, it hereby makes application for permission to make the changes, alterations and improvements in said Chicago River from or near Lake Street in the City of Chicago to or near Ashland Avenue in the City of Chicago, said work to conform to the plan and specifications as follows:

(a) A map herewith exhibits the existing boundaries of that part of the South Branch of the Chicago River which it purposes and desires to improve.

(b) The work to be done contemplates widening the river to a width of two hundred (200) feet between dock lines, except in so far as bridge abutments may project into the stream outside of the new dock lines; said widening in all cases to be made with a view of improving the navigability of the stream.

(c) The work to be so done as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central portion of the stream.

(d) The widening of the river is to be so disposed that the effect will be to produce a straighter channel than now exists and, furthermore, to result in a continuous dock line having straighter alignment and being better disposed for navigation than the docks which now exist.

(e) The work to be done is to be prosecuted progressively as to time. The rate of progress being limited by the rapidity with which right of way may be acquired and the resources for the execution of the work to be made available. The modification and alteration of said river as above indicated will greatly benefit navigation in said river. Your petitioner, therefore, respectfully requests that the plan of improvement as above outlined be approved by you.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor to be,

Very respectfully yours,

THE SANITARY DISTRICT OF CHICAGO,

By WILLIAM BOLDENWECK,

President.

Attest:

JOSEPH F. HAAS,

Clerk.

EXHIBIT J-i.

CHICAGO, June 7, 1900.

To the Honorable,
the Secretary of War.

SIR:—

Under date of April 26, 1900, the Sanitary District of Chicago had the honor to address a communication to you containing an outline of the proposed improvement of a portion of the South Branch of the Chicago River. Accompanying the letter was a map showing the location of the South Branch of the Chicago River, the bridges spanning said river and, also, the width of the stream along the entire course of the South Branch of the river. Since that date the Sanitary District of Chicago passed an ordinance for the improvement of the South Branch of the Chicago River from the south line of Twelfth Street to the east line of Ashland Avenue, so as to make said South Branch, between the lines aforesaid, of a uniform width of two hundred (200) feet; the work to be done so as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central portion of said stream, in accordance with the plans adopted by the Board of Trustees of the Sanitary District of Chicago, a copy of which plans is hereto annexed. The ordinance referred to being marked Exhibit "A," with this

letter; and the maps showing the plans of the proposed improvement being marked Exhibit "B." The maps are in two sections, known respectively as No. 2 and No. 3.

The Sanitary District of Chicago is a municipal corporation, organized and existing under the laws of the State of Illinois and by the laws of said State and the charter of said Sanitary District, it is authorized to enter upon, deepen, widen and otherwise improve any navigable stream, river, or other water-way; and that in pursuance of the power conferred upon it by the statutes of the State of Illinois and in performance of the duties enjoined upon it by the act of the legislature authorizing its creation, and under which it is acting, it determined upon said plans outlined in the enclosed ordinance and further illustrated by the maps hereto annexed; and the said Sanitary District, in compliance with the Statutes of the United States, hereby makes application to you for permission to make the changes, alterations and improvements in said South Branch of the Chicago River, from the south line of Twelfth Street to the east line of Ashland Avenue.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor to be,

Very respectfully yours,

THE SANITARY DISTRICT OF CHICAGO,

By WILLIAM BOLDENWECK,

President.

Attest:

JOSEPH F. HAAS,

Clerk.

The above is a true and correct copy of a map sent to the Hon. Secretary of War, June 7, 1900 and referred to in a letter written by him to Mr. Bakewell, President of the Sanitary District of Chicago, July 11, 1900, granting permission to make certain improvements in the Chicago River.

Chief Engineer

EXHIBIT L.

War Department,

WASHINGTON, July 11, 1900.

SIR:

I have the honor to acknowledge the receipt of your letter of April 26th last, requesting, in behalf of the Sanitary District of Chicago, permission to change, alter and improve the Chicago River, from Lake Street to Ashland Avenue, in Chicago, as shown on maps which accompanied your said letter.

Replying thereto I beg to inform you that there is no objection on the part of the War Department to the prosecution of work of improvement of Chicago River, specified in the above mentioned letter and delineated on the maps which accompanied the same, it being understood that this statement as to the attitude of the War Department shall not be understood as involving the general government in any way with the expense incident to the carrying out of the project, and does not in any way invalidate, waive or affect the right of the Secretary of War to regulate or revoke the permit granted under date of May 8, 1899, to the Sanitary District of Chicago, to divert the waters of the Chicago River and cause them to flow into the artificial channel, such permission being subject to the following conditions, viz:

"1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action and that this permit shall be subject to such action as may be taken by Congress.

"2. That if, at any time, it becomes apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch.

"3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navi-

gation interests by reason of the introduction of a current in Chicago River.

Very respectfully,

ELIHU ROOT,
Secretary of War.

Mr. Wm. Boldenweck,
President the Sanitary District of Chicago,
Security Building, Chicago, Ill."

War Department,

WASHINGTON, July 11, 1900.

SIR:—

In response to your application of the 7th ultimo, for permission to make certain changes, alterations and improvements in the South Branch of the Chicago River, from the south line of Twelfth Street to the east line of Ashland Avenue, as shown on plans which accompanied said application, I beg to inform you that there is no objection on the part of the War Department to the prosecution of the work as specified, it being understood that this statement as to the attitude of the War Department shall not be understood as involving the general government in any way with the expense incident to the carrying out of the project, and does not in any way invalidate, waive or affect the right of the Secretary of War to regulate or revoke the permit granted, under date of May 8, 1899, to the Sanitary District of Chicago, to divert the waters of the Chicago River and cause them to flow into the artificial channel such permission being subject to the following conditions, viz:

"1. That it be distinctly understood that it is the intention of the Secretary of War to submit the question connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

"2. That if, at any time, it become apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge

through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch.

"3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago River.

Very respectfully,

ELIHU ROOT,
Secretary of War.

Mr. Wm. Boldenweck,
President the Sanitary District of Chicago,

Discharge was decreased by ¼ of 1 per cent for each tenth foot Lake St. Clair was below normal, as expressed by equation St. Clair = 574.79 + 0.60 (Harbor Beach — 580).

Elevations of St. Clair have not been corrected for adjustment of December, 1903, which increased elevations 0.06 feet.

Note:—
Nos. 116, 117, 118. Span 1 blocked with ice.
No. 114. Span 9 blocked with ice.
Nos. 91, 92, 100, 101, 102. Spans 1 and 9 blocked with ice.
Nos. 86 to 90, inclusive. Spans 1 and 9, and east half of Span 2 blocked.
No. 86. Discharge for Sta. 3½ is interpolated.
No. 120. Discharge for Span 2 is interpolated.
No. 119. Discharge for Spans 1 and 2, and Sta. 3½ interpolated.

WILLIAMS EX. 26. Sheet 1

TABLE No. 1. LAKE SUPERIOR AT SUPERIOR, WIS., AND MARQUETTE, MICH.

Monthly means of water levels above mean tide at New York. Marquette readings depend on zero of gage-601.75 and B. M. 3-609.91 sea level elevations. U. S. Lake Survey level adjustment of 1903.

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Mean

a Superior, Wis. b Marquette, Mich. c Interpolated by the same differences to the observed monthly means for that year as are found in the means of monthly means for the ten year series 1862-71. d Interpolated by applying the average difference of Marquette, Mich., and Sault Ste. Marie, Mich., water levels for the year to the monthly mean at Sault Ste. Marie Mich. e From records of self-registering gage.

Note.—Superior, Wis., records are found in Report of Chief of Engineers 1876, and are reduced to sea level elevations and 0.45 ft. added to reduce to the new levels. This difference of 0.45 ft. is the same as used to correct the levels at Duluth, Minn. There is an uncertainty of 0.4 ft. in the elevation of the zero of the gage at Superior, Wis. The possible alternative would make the levels 0.4 ft. lower than given in the table. The Marquette, Mich., records are considered reliable.

TABLE No. 2. LAKE MICHIGAN AT MILWAUKEE, WIS.

Monthly means of water levels above mean tide at New York, depending on check point. (1876) on Chestnut St. Bridge (destroyed) as 586.55, and check point (1902) on same bridge as 584.47 Sea level elevations in ft. U. S. Lake Survey level adjustment of 1903.

a From records of self-registering gage on harbor pier.

Note.—These water levels also depend on B. M. on N. E. corner of Dr. Lapham's house at No. 321 Poplar St. as 596.385 ft. The Milwaukee staff gage readings as reduced from publication in previous reports are slightly inconsistent owing to various assumptions in regard to the stability of the gage and reference bench marks. The results of spirit leveling at infrequent intervals show a slight difference in the relative elevations of the reference B. M. on Dr. Lapham's house and the check point on the masonry pier of the Chestnut St. Bridge. In the above table these different results are ascribed to the natural discrepancies of the levels and reductions are made on the assumption that these marks have remained stable and at the relative elevations as originally determined. This assumption is supported by the results of the latest levels (1901). Levels in August, 1901, and November, 1902, indicate that the gage zero had raised 0.03 and 0.05 ft. respectively since the previous test in 1896, explained no doubt by extensive improvements being made in the vicinity. The corrections due to this change in zero have been uniformly distributed. Previous to 1896 the gage zero remained stable with reference to the check point.

The Milwaukee gage is situated at the foot of Poplar St. in the Milwaukee River, about two miles above the mouth and the readings do not indicate the stage of Lake Michigan during high stages of water or ice gorges in the river.

WILLIAMS EXHIBIT 26 Sheet 3.

TABLE No. 3. LAKE HURON AT HARBOR BEACH, MICH.

Monthly means of water levels above mean tide at New York depending on B. M. "Jenks" 610.86 and gage bolt "E" 583.21 sea level elevation in feet U. S. Lake Survey level adjustment of 1903.

a From records of automatic gage after April, 1901.

Note—By Lake Survey levels run in March, 1901, it was found that water levels as being reported from this station were 0.07 ft. too high from the adopted elevations of the reference bench marks. This error was first dropped from the published mean of May, 1901.

The original gage established by Asst. Engr. Gilbert and used until 1884 was probably correct, this error being introduced by the frequent transfer to new gages subsequently set by the gage observers.

This table to Jan., 1892, is reduced from Chief of Engineers reports; from Jan., 1892, to date from records in this office. A correction of 0.07 ft. has been made to the reported monthly mean after Jan. 1, 1895.

There is a lack of data to show definitely when this error was first introduced, the above date being selected arbitrarily, suggested by a comparison with Milwaukee records.

TABLE No. 4. LAKE ST. CLAIR AT ST. CLAIR FLATS CANAL.

Monthly means of water level above mean tide at New York depending on gage zero 575.42 and P. B. M. Old Club 576.571 Sea level elevation in feet. U. S. Lake Survey level adjustment of 1903.

a Readings interpolated by applying average difference of readings for year to monthly means at Erie, Pa.
b From automatic gage records.

Note.—The Cleveland gage has been frequently inspected and the water levels are considered reliable.

TABLE No. 6. LAKE ONTARIO AT OSWEGO, N. Y.

Monthly means of water levels above mean tide at N. Y., depending on gage zero 244.12 and B. M. "A" 251.90, sea level elevations in feet. U. S. Lake Survey adjustment of 1903.

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug	Sept.	Oct.	Nov.	Dec.	Mean

a Interpolated. b From records of self-registering gage.

Note—Recent spirit leveling, executed with much care, determined the zero of Oswego staff gage 7.78 ft. below B. M. "A". The value previously used in all reports is 7.75 ft. The gage is cut in the vertical face of cut stone masonry, founded upon solid ledge rock, and is free from any possibility of settlement, hence readings are all reduced for the later value.

The records have been carefully kept and are reliable, but do not always indicate the stage of Lake Ontario, as the gage readings are influenced by high stages of water in Oswego River. These high stages usually occur in the spring months, and give gage readings from 0.2 to 0.3, or even more, above the level of Lake Ontario.

Mean to 1905, incl.													

Note.—The water level at this station are all from records of self-registering gage. In the adjustment of levels made in 1903, the correction of levels of Lake Erie ports with those of the upper lakes was made by comparison of water levels with those at this station, making the elevation of gage B. M. 579.172. Subsequent precise levels from P. b. M. Trenton (1877) using the adjusted elevation gives the elevation of Gage B. M. 579.337. The later value is adopted, giving the water levels at Amherstburg on the same plane as other stations on Detroit River and above, but probably about 0.15 ft. too high as compared with Lake Erie gages. The slope of the river from Amherstburg to Lake Erie has not been definitely determined, but is assumed to be from 0.10 to 0.15 feet.

TABLE No. LAKE ST. CLAIR AT WINDMILL PT.

Means to 1905, incl.													

Note.—The water levels at this station are reduced from tri-daily staff-gage readings made under the direction of the U. S. Lake Survey Office, Detroit. The readings from Jan., 1911, to Mar., 1912, are in doubt, as the new float gage furnished the gage reader in former month was injured soon after it was received, and this was not discovered until the latter month. Readings for this period have been corrected +0.13 ft. determined by comparison with St. Clair Flats Canal, Fort Wayne, and Amherstburg.

ENGINEER OFFICE, U. S. ARMY,
Detroit, Mich., July 20, 1903.

GENERAL: I have the honor to submit with my annual report for the fiscal year ending June 30, 1903, a special report on the outflow, rainfall, and evaporation in the valley of the Northern and Northwestern Lakes.

Very respectfully, your obedient servant,

WM. H. BIXBY,
Major, Corps of Engineers.

Brig. Gen. G. L. GILLESPIE,
Chief of Engineers, U. S. A.

U. S. ENGINEER OFFICE, JONES BUILDING,
Detroit, Mich. June 25, 1903.

MAJOR: I have the honor to submit the following discussion of the outflow, rainfall, and evaporation in the valley of the Great Lakes:

DRAINAGE BASINS.

The outlines and areas of the drainage basins of the several lakes were first determined. Plate I is a map of these basins. This map was compiled from the best topographical maps available. It was also compared with a similar map prepared by the Deep Waterway Commission. The watershed or boundary of the basin was determined by a study of the sources of the streams. In the United States the land survey maps show these with considerable accuracy. It is likely that the township in which a stream has its rise is in almost all cases correctly given, and the location of the source is known within less than 6 miles. In a portion of Canada the maps have equal accuracy.

In order to make an approximate estimate of the error in the determination of the area of the drainage basin, it might reasonably be assumed that the best located part of the boun-

dary was never more than 6 miles in error, and this not oftener than once in a hundred miles. This error would sometimes be inside the basin and sometimes outside as a compensating error. Since there is about 2,500 miles of the developed boundary line known with this accuracy, there might be about 500 miles uncompensated, which would make a possible error of about 1,500 square miles. In the northwestern part there is about 900 miles of the boundary where the maps are less accurate, and it might be reasonably assumed that the location is never more than 20 miles in error, and this not oftener than once in a hundred miles. Then the uncompensated possible error in this part of the boundary would be about 3,000 square miles, and the total possible error with this assumption would be about 4,500 square miles, or about 1½ per cent. of the total area of the basins. It is therefore probable that the areas of the several basins are correctly determined within less than 2 per cent.

After the boundary line was drawn on the map the area included by it was determined as follows:

Quadrilaterals of one degree or less in extent, bounded by meridians and parallels, were selected so as to completely cover the basin; this gave a polygon, the sides of which were meridians and parallels. The total area of this polygon was determined accurately from geodetic tables of areas. Those small parts of the polygon which extended outside of the boundaries of the basin were measured on the map with a planimeter and subtracted, the remainder being the area of the basin. This work was done with care and checked, and it is believed that the areas of the lakes and basins as herewith given on Plate I are as accurate as extant maps will permit.

In determining the area of the lakes their connecting waters were included; the lines of division between the lakes were chosen at the points where the discharge measurements were made, viz, Sault Ste. Marie, Port Huron, Buffalo, and Ogdensburg. For this determination the lake survey maps were used and the same method followed as for the entire basin. It is seen from this map that the northeast watershed approximates a straight line for a distance of more than 800 miles—that is, a straight line could be drawn for that distance so that at no point would its distance from the watershed be more than 30 miles. It will also be noticed that at certain points the shores of Lakes Superior, Michigan, and Erie approach to within less than 10 miles of the boundaries of their basins.

LAKE ELEVATIONS.

The changes in the elevation of the surfaces of the Great Lakes, and consequently of the rivers connecting them, are small, the mean annual change being less than 2 feet, while the extreme range in monthly means for the last forty-two years is less than 5½ feet. The records of the elevations of all the lakes, except St. Clair, since 1860 are continuous and reasonably trustworthy. They have been published from year to year in the Report of the Chief of Engineers, from which they have been collected and are herewith given in Tables I to V.

The elevations of Lake St. Clair, herewith given in Table III, are not all directly observed; before 1872 no observations were made at Lake St. Clair; all the elevations given in the tables before that date and a few after it have been computed from the observed elevations of Lakes Huron and Erie. The formula used for such computations is taken from page 5397 of the Report of the Chief of Engineers for 1900, and is as follows:

St. Clair Flats=574.06+.407(H—580)+.452(E—570) where H=elevation of Lake Huron and E=elevation of Lake Erie, as herewith given in Tables II and IV.

For Lake St. Clair the elevation for the summer months only have been used, as the elevations during the winter months are often seriously disturbed by the ice, as discussed on page 2822 of Report of Chief of Engineers for 1902.

OUTFLOW AND DISCHARGE FORMULAE.

The outflow from the lakes has been measured at different times by the United States lake survey; the measurements since 1896 have been made with modern and improved appliances; the results have been very accordant. The discharge formulas derived from this later work have been used in this discussion. It is found that within the small observed range of the surface elevation the discharge is so near a linear function of the surface elevation that one can be derived from the other with considerable accuracy; therefore, the discharge can be determined whenever the surface elevation is known. This has been done for the years 1860 to 1902, and the results are herewith given in Tables VI to IX, and also shown graphically in Plate II.

The discharge from Lake Superior was measured at Sault Ste. Marie from 1896 to 1899, and discharge formulae were deduced therefrom in 1900.

Between 1887 and 1892 the outlet of Lake Superior was somewhat contracted by the building of the International Bridge piers at Sault Ste. Marie, and also by the closing of some of the small streams on both sides of the river. These changes make the discharge formulae different for different periods, as follows:

Before 1888, discharge in s-f=46,047+19,429 x (elev.—600).

From 1888 to 1895, inclusive, discharge in s-f=39,798+17,656 x (elev.—600).

From 1896 to 1898, inclusive, discharge in s-f=43,466+17,656 x (elev.—600).

After 1898, discharge in s-f=49,235+17,656 x (elev.—600).

In these formulae "elevation" means the elevation of lake surface as herewith given in Table I.

The data and methods used in determining such formulae, not having as yet been printed or otherwise published, are herewith attached and marked "Appendix A."

The outflow from Lakes Michigan and Huron was measured at Port Huron from 1898 to 1900. The results are given on pages 2819 et seq. of the Report of the Chief Engineers for 1902. It was found that the discharge of St. Clair River was not exactly a linear function of the surface elevation of Lake Huron, but was modified by two causes—first, the surface elevation of Lake St. Clair, and, second, ice during the winter season.

The formula for the discharge of St. Clair River during the summer months includes the surface elevation of both Lakes Huron and St. Clair. It is given on page 2821 of the Report of the Chief of Engineers for 1902, as follows:

Discharge in s-f=190,700+37,500(H—580 ft.)—18,000(St. Clair—575 ft.), in which H=the surface elevation of Lake Huron as herewith given in Table II, and St. Clair=the surface elevation of Lake St. Clair as herewith given in Table III. This formula is used in computing the discharge of the St. Clair River for the summer months—June to November, inclusive. For the winter months—December to April, inclusive—this formula is not applicable because of the ice effects.

A formula for the discharge of St. Clair River when the elevation of Lake Huron is alone considered is given on page 5362 of the Report of the Chief of Engineers for 1900, as follows:

Discharge in s-f=194,900+19,060 x (H—580 ft.), H being the elevation of Lake Huron as given in Table II.

During the winters of 1900, 1901, and 1902 the ice effects were measured. The results are given on page 2837 of the Report of the Chief of Engineers for 1902, and show that the discharge from Lake Huron as computed from the preceding formula was diminished by ice, as follows:

	Second-feet.
December	8,600
January	41,750
February	60,833
March	55,700
April	39,550
May	11,000

Since these three years' observations are all that is known of ice effects it is assumed that they show the average effect of ice. Therefore the discharge for the winter months was first computed from the preceding formula and then each month reduced by the quantities in the above table. This determination of the winter discharge of St. Clair River has the least data and is the most involved and uncertain of any of the discharge determinations. The ice effects are certainly very erratic, and the assumption that the mean of the three observed years is the mean of the forty-three years considered may be somewhat in error.

The outflow from Lake Erie was measured at International Bridge, Niagara River, from 1898 to 1900. The results are given in the Report of the Chief of Engineers for 1900, pages 5326 et seq. The formula for the discharge of Niagara River derived from these results is as follows:

Discharge in s-f=158,500+22,462(C—570 ft.).

C is the elevation of Lake Erie as herewith given in Table IV.

This formula may require two small corrections: First, the discharge should be increased by the flow through the Welland and Erie canals. The flow through the Welland Canal is is estimated by the department of railways and canals of Canada as 1,100 s-f. The flow through the Erie Canal is estimated by the New York engineer for water supply as 1,200 s-f, making a total of 2,300 s-f. The second correction is due to a difference between the zeros of the gauges at Cleveland and Buffalo. This difference has been observed and determined for calm weather, when it amounts to about 8,500 s-f. For use in this connection the mean for both calm and windy

weather should be known; therefore, on account of the remaining uncertainties in these two corrections, neither of them has been applied. The two corrections are in opposite directions and tend to eliminate each other.

The outflow from Lake Ontario was measured from 1900 to 1902. The resulting formula for the discharge of St. Lawrence River is given on page 2793 of the Report of the Chief of Engineers for 1902, and is as follows:

Discharge in s-f=946833+25761 (0—240 ft.),

in which 0 is the elevation of Lake Ontario at Oswego, as herewith given in Table IX.

It was found that for Lake Ontario there was a small correction, due to ice effects, for the winter months. These corrections are given on page 2809 of the Report of Chief of Engineers for 1902, and are as follows:

Percentage of loss on account of ice:	Per cent.
January	6.2
February	9
March	5.3
April	1.2

These percentages have been computed and subtracted from the discharge, as given by the preceding formula.

In the preceding formula the elevation of lake surface above sea level is expressed in feet, and "s-f" means cubic feet per second.

Discharge measurements are still continued by the lake survey, so that it is probable that the preceding formula will in time be slightly modified, so as to be a little more exact, but no large change is expected or possible.

By means of the preceding formula the discharge tables herewith given (VI to IX) have been derived from the tables of surface elevation herewith given (I to V).

RAINFALL.

The rainfall (which includes snowfall) has been compiled from the records of the United States Weather Bureau and the Canadian meteorological service. The period chosen is the sixteen years from 1882 to 1898. The years before 1882 were not used, because the number of stations where rainfall records were kept were few in number; the four years since 1898 could now be added, and thus increase the value of the result. The stations at which observations were made are shown on Plate I herewith. The Weather Bureau stations

are indicated by special marks; the other stations are volunteer stations. At many of these observations were made for only a part of the time. It will be seen that the stations are quite unsymmetrically placed in the basin, most of them being in the southern part. This is the most serious defect in the rainfall data. Since the rainfall diminishes both to the north and to the west, it is evident that the direct mean of the rainfall as observed at these stations would be greater than the mean rainfall of the whole basin. To avoid this source of error as far as possible two methods of reduction were employed. The first was to prepare a map for each month on which the stations used during that month were plotted in their proper geographical positions; the inches of rainfall at each station were written in figures, then curves of equal rainfall were drawn among the plotted points as contours are drawn. These curves show the regions of equal rainfall; the irregular areas bounded by these curves were then measured with a planimeter and each one multiplied by its rainfall, and a mean of all taken, which was assumed to be the mean rainfall in the basin for that month. This method was applied from 1883 to 1893; it required a great amount of work, and was finally changed to the second method, which was shorter and perhaps equally accurate, as follows:

The Weather Bureau has determined the lines of equal rainfall from all available data and published the results in the form of a map (Plate VII of report for 1897); from this map the rate of change in rainfall due to the change in latitude and longitude was determined for each basin. The mean latitude and longitude of the basins was also found; then the rainfall at each station was corrected by its distance in latitude and longitude from the center of the basin.

The results for the several basins are herewith given in Tables X to XIII, and are as follows:

The mean annual rainfall in—	Inches.
Lake Superior basin	=26.27
Lakes Huron and Michigan basins	=32.12
St. Clair and Erie basins	=34.08
Ontario basin	=36.87

The rainfall records are kept in inches, while the unit of discharge is cubic feet per second, or s-f. In order to compare them with each other it is necessary to express both quantities in the same unit; for this purpose the following table is prepared, which shows the equivalent in s-f of the rainfall in the several basins:

Annual rainfall—	s-f.
Superior basin	=147,164
Huron and Michigan	=325,857
St. Clair and Erie	=102,308
Ontario	= 89,557

EVAPORATION.

It is assumed that if the mean annual discharge or outflow from a basin be subtracted from the mean annual rainfall into the basin the remainder will be the mean annual evaporation. For the basin of Lake Superior the mean annual rainfall from the preceding table is 147,164 s-f. The mean annual discharge for sixteen years (1882-1898) from Table VI herewith is 69,954 s-f; the difference is 77,210 s-f=13.78 inches. There is a small correction to apply to this quantity, due to the fact that Lake Superior was 1.31 inches higher at the end of the period considered than at the beginning; this makes a correction of —0.03 inch, and the evaporation for the Lake Superior basin is 13.75 inches.

For the Huron and Michigan basins the mean annual rainfall from the preceding table is 325,857 s-f. The inflow from St. Marys River from Table VI herewith is 69,954 s-f, making the total inflow 395,811 s-f. The discharge or outflow from Table VII herewith is 191,980 s-f. The difference between the inflow and outflow is, then, 203,831 s-f=20.29 inches.

There is a correction to apply to this quantity, due to the fact that Lakes Huron and Michigan were 22.8 inches lower at the end of the period considered (1882 to 1898) than at the beginning; this makes a correction of +0.47 inch, and the evaporation of the Huron and Michigan basin is 20.56 inches.

For the St. Clair and Erie basin the mean annual rainfall from the preceding table is 102,308 s-f. The inflow from St. Clair River from Table VII herewith is 191,980 s-f, making the total inflow 294,288 s-f. The discharge or outflow from Table VIII herewith is 216,468 s-f. The difference between the inflow and outflow is, then, 77,820 s-f=25.90 inches. There is a correction to apply to this quantity, due to the fact that Lake Erie was 12.30 inches lower at the end of the period than at the beginning; this makes a correction of +0.20 inch, and the evaporation of the St. Clair and Erie basin is 26.10 inches.

For the Ontario basin the mean annual rainfall from the preceding table is 89,557 s-f. The inflow from Niagara River is 216,468 s-f, making the total inflow 306,025 s-f.

The discharge or outflow through the St. Lawrence River from Table IX herewith is 248,518 s-f. The difference between the inflow and outflow is, then, 57,507 s-f=23.67 inches. There is a correction to apply to this quantity, due to the fact that Lake Ontario was 10.56 inches lower at the end of the period than at the beginning; this makes a correction of +0.15 inch, and the evaporation of the Ontario basin is 23.82 inches.

WEATHER BUREAU RECORDS.

Temperature, humidity, and wind, together with rainfall, are the four elements which very largely control evaporation. These have accordingly been compiled from the Weather Bureau records. On account of the unsymmetrical geographical distribution of the stations in the basins, a direct mean of the observations would not give a correct mean for the basin. For use and further reference in connection with this report and discussion, the Weather Bureau observations have therefore been reduced in the same manner as previously described for rainfall, and, as so reduced, are given in Tables X to XXV herewith.

GENERAL RESULT.

The results for each basin are herewith summarized, as follows:

Superior basin.

Area of drainage basin	square miles	76,100
Area of Lake Superior	do	32,100
Discharge St. Marys River (mean 1882-1898)	s-f	69,954
Discharge St. Marys River (mean 1860-1903)	do	77,345
Annual rainfall (mean 1882-1898)	inches	26.27
Annual evaporation (mean 1882-1898)	do	13.75
Temperature (mean 1882-1898)		35°.95 F.
Wind, velocity per hour (mean 1882-1898)	miles	9.7
Humidity, percentage of saturation (mean 1882-1898)	per cent.	76.5

Huron and Michigan basins.

Area of drainage basin	square miles	137,800
Area of Lakes Huron and Michigan	do	45,500
Discharge St. Clair River (mean 1882-1898)	s-f	191,980
Discharge St. Clair River (mean 1860-1902)	do	197,820
Annual rainfall (mean 1882-1898)	inches	32.21
Annual evaporation (mean 1882-1898)	do	20.56
Temperature (mean 1882-1898)		42°.08 F.
Wind, velocity per hour (mean 1882-1898)	miles	10.3
Humidity, percentage of saturation (mean 1882-1898)	per cent.	76.5

St. Clair and Erie basins.

Area of drainage basin	square miles	40,800
Area of Lakes St. Clair and Erie	do	10,600
Discharge Niagara River (mean 1882-1898)	s-f	207,468
Discharge Niagara River (mean 1860-1902)	do	219,843
Annual rainfall (mean 1882-1898)	inches	102.308
Annual evaporation (mean 1882-1898)	do	26.10
Temperature (mean 1882-1898)		48°.01 F.
Wind, velocity per hour (mean 1882-1898)	miles	10.4
Humidity, percentage of saturation (mean 1882-1898)	per cent.	73.6

Ontario Basin.

Area of drainage basin	square miles	33,000
Area of Lake Ontario	do	7,400
Discharge of St. Lawrence River (mean 1882-1898)	s-f	248,518
Discharge of St. Lawrence River (mean 1860-1902)	do	251,930
Annual rainfall (mean 1882-1898)	inches	36.87
Annual evaporation (mean 1882-1898)	do	23.82
Temperature (mean 1882-1898)		44°.10 F.
Wind, velocity per hour	miles	10.6
Humidity, percentage of saturation (mean 1882-1898)	per cent.	74.9

These results are apparently consistent with each other, at least within the limits of the accuracy of the data. Formerly there was a marked inconsistency between the derived discharges of the St. Clair and Niagara and St. Lawrence rivers, the St. Clair being nearly as large as the Niagara, and the St. Lawrence being very much larger than the Niagara. The investigations of ice effects, made by the United States lake survey, has reduced the derived discharge of both the St. Clair and the St. Lawrence rivers, so that now their relation to the derived discharge of the Niagara is entirely reasonable, and there is no longer cause for the theory that a part of the discharge from Lake Erie passes by underground percolation into Lake Ontario.

Very respectfully,

E. S. Wheeler,
Assistant Engineer.

Maj. William H. Bixby,
Corps of Engineers, U. S. Army.

APPENDIX A.

Memoranda prepared July 17, 1900, by Asst. Engineer E. S. Wheeler, for the discussion of the discharge observations made in St. Marys River at Sault Ste. Marie in 1896-1899, under the river and harbor office of Col. G. J. Lydecker, showing the data and methods used in determining formulae for Lake Superior outflow.

Four separate groups of observations were made and two different cross sections used during 1896-1899. In 1896 Mr. E. E. Haskell made 34 measurements at the Spry dock section and 11 measurements at the bridge section. The former were published in the Annual Report of the Chief of Engineers for 1897. In 1899 Mr. T. Russell made 65 measurements at the Spry dock section and 34 at the bridge section.

The measurements at Spry dock section include the entire outflow from Lake Superior; those at the bridge section include only the flow which passes under the bridge. A gauge at the south end of the bridge was read for all four groups. This gauge is in span 1, which is a part of the Chandler-Dunbar canal; its relation to the bowlder gauge was determined by several sets of simultaneous observations, as follows:

Gauge at bridge.	Gauge at bowlder.	Gauge at bridge.	Gauge at bowlder.	Gauge at bridge.	Gauge at bowlder.	Gauge at bridge.	Gauge at bowlder.
Feet.		Feet.		Feet.		Feet.	
601.70	+ .11		.20		.17		.17
.80	.11		.20		.16		.16
.91	.10		.19		.17		.17
.91	.11		.19		.17		.16
601.90	.11		.19		.17		.16
602.00	.11		.19		.16		.16
.00	.11		.19		.16		.16
.10	.11		.18		.16		.16
.17	.11	602.00	.21		.16		.17

The mean of this determination is 0.17 feet; and a comparison of these observations does not indicate any change due to stage. The difference between the gauge at the bowlder and at the bridge was therefore taken as 0.17 feet at all stages, and the bridge gauge readings were increased by this amount, so that in the following discussion all gauge readings have been reduced to and referred to the gauge at the west end of the southwest canal pier.

In order to make the four groups of measurements comparable with each other, the two Spry dock groups were diminished by the amount that was passing outside of the bridge at the time the observations were made. The outside flow was measured in 1896 and found to be 5,000 s-f at stage 601.17, with an increment of 950 s-f for each foot of rise in the gauge. In 1899 the outside flow was found to be 10,768 s-f

at stage 601.17, with the same increment of 950 s-f for each foot of rise in the gauge. The flow under the bridge resulting from such measurements and corrections is as given in the following tables:

[From current measurements made at Spry dock in 1896 by E. E. Haskell.]

These groups have also been discussed and platted separately, the discharge in each case being represented graphically by a straight line.

In their discussions the groups were given different weights due to the number of observations, range in gauge readings, and accuracy of rating, and the discharge at the mean stage was found by giving to each group a weight equal to the product of its rating into the square root of the number of observations.

The relative weight was assigned as follows:

Spry dock:

1896..... 10
1899..... 8

Bridge:

1899..... 3
1896..... 1

The number of observations was as follows:

Spry dock:

1896..... 52
1899..... 62

Bridge:

1899..... 34
1896..... 11

The results of the four groups were then:

	Date.	Gauge.	Discharge.	Weight.
Spry dock	1896	601.41	68,980	10×√52
Do	1899	601.19	86,926	8×√62
Bridge	1899	602.31	82,194	3×√34
Do	1896	601.31	77,669	1×√11

Giving at stage 601.402 a discharge of 63,000 s-f.

The increase in discharge for 1 foot change in gauge was found by giving to each group a weight equal to the product of its rating and range in gauge reading, as follows:

Spry dock:		
1896	17,139	10×10
1899	15,963	8× 7
Bridge:		
1899	16,426	3×17
1896	18,227	1× 9

Giving 16,706 s-f. as the change in discharge for 1 foot change in gauge reading; and at gauge 600, a discharge of 39,578 s-f; and a discharge equation of—

(1) Discharge=39,578+16,706×(gauge —600),

applicable to the discharge under 8 spans of the bridge, not including spans 1 and 2, which are in the Chandler-Dunbar Water Power Canal.

The observations show that the discharge curve may be taken as a linear function of elevation without appreciable error, at least within the small range of elevation used. To obtain the total flow in the river there must be added the flow through the Canadian Water Power, the Chandler-Dunbar Water Power, the two ship canals, and the two small streams on the Canadian side.

The flow through the river before the building of the bridge will first be determined. From a report (with sketches) of Asst. Engineer E. E. Haskell, dated June 11, 1896,* it is found that the building of the bridge and approaches and other works (largely in shallow parts of the river), done between 1887 and 1892, diminished the cross-section of the river (at stage 601.53) 38 per cent. in width and 26.4 per cent. in area, diminished the discharge 14 per cent., and increased the mean velocity 17 per cent. (The sketch which accompanies Mr. Haskell's report shows that the width of the cross-section before 1888 was 4,200 feet and after the obstructions were made was only 2,600 feet.) From this data it is possible to determine the discharge equation before 1888. First, by the preceding equation the discharge is zero at stage 597.63, and therefore (assuming the discharge curve to be a straight line) 597.63 must be the elevation of the bottom of the river. This

*Not published.

therefore there is already one gauge reading, viz, 597.63, at which the discharge before 1888 is known. If now the increment for unit of gauge can be determined the discharge equation will be complete. Since the discharge after obstruction is 14 per cent. less than before, the increment after obstruction must be 14 per cent. less than the increment before. Since the increment after obstruction is 16,706 s-f, it follows that the increment before was 19,429 s-f. Since the discharge is zero at gauge 597.63, the discharge at gauge 600 is 46,047 s-f, and a new discharge equation may be written.

(2) Discharge=46,047+19,429×(gauge—600),
applicable to all gauge readings before 1888.

Between 1888 and 1895 the only outside flow was through two small streams on the Canadian side and through the United States canal. The amount of this flow is estimated as 1,674 s-f at stage 601.53, with an increment of 950 s-f for foot of rise. Adding the corrections to equation (1) there results the following:

(3) Discharge=39,798+17,656×(gauge—600),
applicable to all gauge readings from 1888 to 1895, both years inclusive.

The outside flow from 1896 to 1898 includes the two ship canals, the two water powers, and the two small streams; the total is estimated as 5,000 s-f at stage 601.17 with an increment of 950 s-f for each foot of rise. Adding these amounts to equation (1) there results the following,

(4) Discharge=43,466+17,656×(gauge—600),
applicable to all gauge readings from 1896 to 1898, inclusive.

In 1899 both water powers had been enlarged, and it is estimated that the total outside flow at stage 601.17 was 10,768 with an increment of 950 s-f. Adding these corrections to equation (1) there results,

(5) Discharge=49,235+17,656×(gauge—600),
applicable to gauge readings in 1899 and until further changes are made in the outside flow.

Collecting the equations, the relation between discharge and gauge at southwest canal pier is therefore assumed as follows:

Equation for discharge through eight spans of the bridge,

$$\text{Discharge}=39{,}578+16{,}706\times(\text{gauge}-600) \quad (1)$$

Equation for total discharge before 1888,

$$\text{Discharge}=46{,}047+19{,}429\times(\text{gauge}-600) \quad (2)$$

Equation for total discharge from 1888 to 1895, inclusive,

$$\text{Discharge}=39{,}798+17{,}656\times(\text{gauge}-600) \quad (3)$$

would be equally true before the obstructions were made, and

Equation for total discharge from 1896 to 1898, inclusive,

$$\text{Discharge}=43{,}466+17{,}656\times(\text{gauge}-600) \quad (4)$$

Equation for discharge in 1899 and until further changes are made,

$$\text{Discharge}=49{,}235+17{,}656\times(\text{gauge}-600) \quad (5)$$

REPORT

ON

REGULATION OF LAKE ERIE.

INTERNATIONAL WATERWAYS COMMISSION.

OFFICE OF THE AMERICAN SECTION,

BUFFALO, N. Y., January 8, 1910.

1. The act of the Congress of the United States, approved June 13, 1902, which requested that the Government of Great Britain be invited to join in the formation of this Commission, defined one of the duties of the Commission as follows, viz.:

"The said Commissioners shall report upon the advisability of locating a dam at the outlet of Lake Erie, with a view to determining whether such dam will benefit navigation, and if such structure is deemed advisable, shall make recommendations to their respective Governments looking to an agreement or treaty which shall provide for the construction of the same, and they shall make an estimate of the probable cost thereof."

2. The Great Lakes, lying between the United States and Canada, with their connecting channels and their natural outlet to the sea, the St. Lawrence River, of which a description will be found in the appendix to this report, constitute the most important system of inland navigation in the world. The traffic which passed through the Detroit River, its busiest link, in 1907, amounted to 71,226,895 tons, valued at about $700,000,000. About 70 per cent. of this traffic is carried in large freight carriers which are loaded down to the greatest draft that can be carried into the harbors or through the channels between the lakes. With the depth now available they are usually loaded to a draft of about 19 feet, but careful watch is kept upon the stage of the waterways and advantage is taken of any temporary increase of stage to load the vessels deeper. The number of deep-draft vessels, as well as their size, and the share of lake traffic which they carry is increasing each year, while the lake traffic itself is increasing with great rapidity. Vessels which would carry an additional load of 85 tons for each inch of additional draft have recently been

added to the fleet. Every inch added to the available depth of water would, therefore, be of material benefit to commerce.

3. The method heretofore employed for deepening the natural channels is that of excavation, but it has been suggested that a more economical and otherwise better method would be to raise the surface of the water by obstructing the flow of the outlets. For Lake Erie in particular a definite plan, with estimates of cost, was proposed by the Board of Engineers on Deep Waterways in their report dated June 30, 1900, published as House Document No. 149, Fifty-sixth Congress, first session. The official character of this report and the ability displayed in its preparation seems to have led to the provisions of law under which this Commision is now acting, and to make of it a proper starting point for this discussion. It was proposed by the Board to "regulate" the level of Lake Erie.

4. By the term "regulation of a lake's level" is meant the maintenance of its level at or near some fixed stage, which implies such control of the discharge as will make the latter nearly equal to the total supply—rainfall and inflow less evaporation—at all times. In some cases, this may be accomplished by a submerged weir in the outlet, of such length that a small increase or decrease of stage will increase or decrease the discharge over the weir by an amount equal to the change in the total supply. A work of this kind operates automatically, but manifestly it requires more or less range of stage and the topography must be such that a great length of weir can be found; it does not lend itself to the most complete regulation.

5. The works proposed by the Board were for the regulation of Lake Erie within a range so small that it might be considered almost complete regulation. They consisted of a submerged weir in connection with a set of sluice gates "so designed that with the sluice gates all closed the low-water flow of the regulated stage of the lake will be discharged over the fixed submerged weir, and with the sluice gates all open the additional volume of overflow necessary to maintain the lake at nearly the same level will pass through the sluices at times when the lake is receiving its maximum supply." They were to be placed near the angle in the Bird Island Pier, at the head of Niagara River, and were designed to hold the level of the lake at or near 574.5, old levels, or 574.7, 1903 levels, above mean tide at New York. This is higher than any monthly mean stage reached since authentic records have been kept, that is, since 1860. It was a maximum

not to be exceeded. It is not definitely stated what the minimum monthly stage would be under regulation, but it may be inferred from certain paragraphs in the Board's report that it was to be about 573.7, 1903 levels. (See paragraph 104 of the appendix.)

6. The Great Lakes constitute a series of enormous natural reservoirs, each of which serves to regulate the flow in the river constituting its outlet, and to maintain the lake below. They are inter-dependent. The study of one, to be complete, must include the study of all. The total area drained by them is about 287,688 square miles, an area considerably larger than the German Empire. Of this total, about one-third is occupied by the lakes themselves, that is, is devoted to reservoir purposes. The result is a uniformity of level and a uniformity of flow which is truly wonderful. In Table A are given the areas of the lake surfaces and of the drainage basins.

TABLE A.

LAKE	Area of Lake Surface in Square Miles	Drainage Area Including Lake Surface, in Square Miles	Ratio of Lake to Drainage Area
Superior	32,000	76,134	1: 2.37
Michigan	22,336	65,799	1: 2.95
Huron	22,978	72,008	1: 3.13
St. Clair	503	6,194	1: 12.31
Erie	9,968	34,573	1: 3.47
Ontario	7,243	32,980	1: 4.55
Total	95,068	287,688	1: 3.02

Authority: 1906 U. S. Lake Survey report.

The areas of the small lakes and streams are taken as a part of the land area.

In Table B are given the average and the extreme variations in the levels during the period from 1860 to 1907.

TABLE B.

	Superior	Huron	Erie	Ontario
	Feet	Feet	Feet	Feet
Extreme range, 1860-1907	3.52	4.64	3.89	5.34
Maximum range in 1 year	(1860) 2.67	(1876) 1.94	(1892) 2.28	(1867) 3.65
Minimum range in 1 year	(1891) 0.49	(1879) 0.59	(1895) 0.87	(1907) 0.70
Average annual range	1.18	1.21	1.56	1.60

In Table C are given the average and the extreme variations in the discharge of the outlets for the period 1860 to 1907:

TABLE C.

	St. Marys River	Detroit River	Niagara River	St. Lawrence River at its Head
	c. f. s.	c. f. s.	c. f. s.	c. f. s.
Average discharge for entire period	82,000	204,200	212,200	254,400
Greatest excess average for any one month	46,700 Sept., 1869. 57%	71,200 July, 1865. 35%	45,600 June, 1876. 21%	96,800 May, 1902. 38%
Greatest excess average for any one year	19,100 1874. 23%	30,200 1886. 15%	26,500 1876. 13%	49,000 1902. 19%
Greatest deficiency average for any one month	33,800 Feb., 1862. 41%	98,900 Feb., 1874. 48%	43,500 Mar., 1900. 20%	102,200 Feb., 1903. 40%
Greatest deficiency average for any one year	16,900 1879. 21%	30,600 1886. 15%	31,800 1895. 15%	62,800 1895. 25%

No work of man ever has approached or ever will approach this perfection of regulation. The question now is, can he add to that which exists in any important degree.

7. Evidently the answer to this question must be based upon careful analysis and close computation. The data for its solution are found in the records of the water levels, and in the measurements of discharge taken during the last 48 years, principally under the direction of the Chief of Engineers, U. S. Army. Actual values assigned to rainfall and evaporation are not well determined and cannot be used. It is the relative value of these elements which it is necessary to know, and that value is found in the discharge measurements.

8. Soon after the organization of the Commission, a committee of two of its engineer members was appointed to collect all of the available data, and to make an hydraulic analysis of the general regulation of all the lakes. It was well known at the outset that this would be a long and laborious task, but it proved to be more so than was expected, and it was only recently completed. The full report of the committee is hereto attached as an appendix. A brief synopsis of it is here given.

9. Beginning about 1860, and continuing to date, daily or tri-daily water-level observations have been taken at Mar-

quette on Lake Superior, Milwaukee on Lake Michigan, Cleveland on Lake Erie, and Oswego and Charlotte on Lake Ontario. Beginning at later dates, observations have been taken at Sault Ste. Marie, Harbor Beach on Lake Huron, St. Clair River, St. Clair Flats Canal, Windmill Point on Lake St. Clair, Amherstburg on Detroit River, Buffalo on Lake Erie, Ogdensburg on St. Lawrence River, and Lock 27 at the head of Galop Rapids, Lock 24 at the head of Rapide Plat and Lock 21 at the head of Long Sault Rapids, on St. Lawrence River. Self-registering automatic gages giving a continuous graphical record of the rise and fall of the water were not installed until 1899. The record for each of the above-mentioned gages, except the last two, from 1860 to 1907, inclusive, has been completed by interpolation. For Lock 24, on the St. Lawrence, the record has been completed from 1880, and for Lock 21, from 1870. There are a few isolated records of dates earlier than 1860, but they are not well authenticated and cannot be used here.

10. As was stated in our report of January 4, 1907, upon the Chicago Drainage Canal, "Variations in the level of the lake's surface, due to winds and to change of barometric pressure, are frequent and irregular and at times violent. Variations of more than 6 inches are very common, often occurring hourly for many hours in succession, while variations of 2 or 3 feet within an hour are not uncommon. Besides these irregular variations there is a regular annual variation due to difference in rainfall, evaporation, and run-off, the water level being highest in midsummer and lowest in midwinter. The levels are affected also by the greater or less severity of the winter and by the consequent greater or less decrease in the discharging capacity of the outlets by ice. In order to study the annual oscillations it is necessary to eliminate the irregular oscillations, and that is accomplished by using the average levels for a month." The monthly mean stage has been obtained by taking the average of the gage readings for a month, and is given for each of the above-mentioned gages in Tables 2-17. The monthly mean stages of Lakes Superior, Michigan-Huron, St. Clair, Erie, and Ontario, from 1860 to 1907, inclusive, are shown on Plate 1.

11. The volume of discharge of the outlet at any given stage is obtained from a formula deduced from actual measurements of discharge at such stages as happened to exist at the time of observation. Formulae of this kind were deduced for each of the outlets of the Great Lakes. During the winter of 1896 discharge measurements of the St. Marys River,

the outlet of Lake Superior, were made at Spry's Dock Section, located about a mile below the St. Marys Rapids. In 1902 discharge measurements of the same stream were made at the International Bridge which connect Sault Ste. Marie, Mich., with Sault Ste. Marie, Ontario. In 1905 similar measurements were made at "Section Brewery," located about 2,000 feet below Spry's Dock Section. All of these observation were made by the U. S. Lake Survey. Up to the year 1887, the discharging capacity of the St. Marys River remained nearly uniform. Since that date, numerous artificial works have been constructed at the Sault, which have modified its discharging capacity to an important degree. During the years 1887 and 1888, the International Bridge was built, which with its piers and approaches materially reduced the cross section. In 1892, the Edison Sault Electric Company placed power works in the bed of the stream. In 1895, a power canal on the Canadian side was opened to use. In 1905, a power canal on the Michigan side was opened to use, compensating works in connection therewith having been placed in the river in 1901 and 1902. The amount of water diverted by the power canals has increased from time to time since they were opened, and so has the quantity used by the American and Canadian locks. To conform to these changes it was necessary to deduce eleven different discharge formulae for the St. Marys River alone.

12. The discharge formula for St. Clair River, the outlet of Lake Michigan-Huron, was deduced from observations made by the U. S. Lake Survey in 1899, 1900, 1901, and 1902.

In 1900, the Chicago Drainage Canal began diverting water from Lake Michigan. The amount diverted between January, 1900, and June, 1904, inclusive, was computed from data furnished by the U. S. Engineer Office at Chicago. The flow through the canal since June, 1904, has been assumed to be 4,167 cubic feet per second, the quantity authorized in the permit of the Secretary of War. It is believed to have been greater, but the difference is not sufficient to vitiate the results sought for here. An application by the Commission to the Sanitary District of Chicago for a copy of their record met with a refusal to furnish it.

13. The discharge formula for the Detroit River was derived from measurements taken at Fort Wayne, Michigan, by the U. S. Lake Survey in 1901 and 1902.

14. For the Niagara River, the outlet of Lake Erie, discharge measurements were made at the International Bridge at Buffalo, and at a point about 1,800 feet down stream, called

the "Open Section." These observations were begun in 1897 for the Board of Engineers on Deep Waterways, and were continued in 1898, 1899, and 1900, by the U. S. Lake Survey.

15. The discharge formula for the St. Lawrence River, the outlet of Lake Ontario, was deduced from measurements made by the U. S. Lake Survey in 1901 and 1902 at "Three Points Section," situated about 15 miles below Ogdensburg, N. Y., and 9 miles below the head of the Galop Rapids.

16. With the discharge formulae and the gage records, the average discharge, in cubic feet per second, has been computed for each month from 1860 to 1907, inclusive, for each outlet. The results for St. Marys River are given in Table 19; those for Detroit River in Table 20; those for Niagara River in Table 21; and those for St. Lawrence River at its head in Table 22.

17. The total supply of water to a reservoir or lake depends upon the inflow or transmitted supply from another watershed, the precipation on the surface of the lake, the run-off from the lake's watershed, and evaporation from the lake's surface, or the outflow from and storage in the lake. Of these factors, for the Great Lakes, the transmitted supply, the discharge, and the storage are known separately, while the value of precipitation, run-off, and evaporation is known collectively. The local supply for any lake is the water-yield from its own watershed, and is equal to the total supply minus the transmitted supply or inflow from the watersheds situated above. The supply factors have been deduced for Lakes Superior, Michigan-Huron, Erie, and Ontario, for each month from 1860 to 1907, inclusive, and the results are given in Tables 24, 25, 26, and 27. They are shown graphically upon Plates 2 to 17 inclusive.

18. It is to be noted that minus values for the monthly mean local supply have frequently occurred, that is to say, the evaporation has frequently exceeded the precipation and run-off. For Lake Superior, minus values occurred at some time during 41 of the 48 years considered; this usually happened in December, but it sometimes occurred in each of the months from October to April inclusive. The greatest minus value occurred in December, 1870, when the evaporation exceeded the precipation and run-off by 106,600 cubic feet per second.

19. For Lake Michigan-Huron, minus values occurred in 33 out of the 48 years considered. This usually happened in September, October, or November, but it sometimes happened also in August and December. The greatest minus value oc-

curred in September, 1871, when the evaporation exceeded the precipitation and run-off by 125,700 cubic feet per second. In that year minus values occurred in each of the four months from August to November. In 1894, minus values occurred from August to December, inclusive.

20. For Lake Erie, minus values occurred with extraordinary frequency. They are found in every year, and in many years in all of the last six months. From June, 1884, to March, 1885, inclusive, that is, for 10 consecutive months, evaporation exceeded precipation and run-off continuously, the average excess for the entire period being 40,400 cubic feet per second. There is no month, except the month of May, in which a minus value has not been found in some year between 1860 and 1907. The excessive evaporation in Lake Erie may be attributed to the facts that the lake is shallow and its longer axis lies in the direction of the prevalent winds.

21. For Lake Ontario, minus values occurred less frequently than with the other lakes, but were found in 27 out of the 48 years. The greatest minus value occurred in January, 1877, when the evaporation exceeded the precipitation and run-off by 40,300 cubic feet per second.

22. To obtain the general law which governs these supply factors, Table 28 was prepared, which gives their average for the entire period from 1860 to 1907. The averages for Lakes Superior, Michigan-Huron, Erie, and Ontario, are shown graphically on Plate 18. From these, it appears that evaporation exceeds the local supply in Lake Superior during December and is nearly equal to it during January; that evaporation is nearly equal to the local supply in Lake Michigan-Huron during October and November; that it exceeds the local supply in Lake Erie during the last half of the year, July to December; and, as a general rule, does not exceed the local supply in Lake Ontario.

23. The maximum stage of one lake does not occur at the same time as that of another lake, and this is true also of the minimum stage. Nor does the maximum outflow occur at the time of the maximum total supply, nor the minimum outflow at the time of the minimum total supply. The lake may continue to fall while the supply of water is increasing and *vice versa*. These great forces require time to act. The following table shows the ratio, R, between the maximum discharge and the maximum total supply for each lake, the time interval, $T_{MAX.}$, which elapses between the maximum total supply to any lake and the maximum discharge from that

lake, and the time interval, $T_{MIN.}$, which elapses between the minimum total supply and the minimum discharge.

LAKE	R	$T_{MAX.}$	$T_{MIN.}$
Superior	0.524	98 days	91 days
Michigan-Huron	0.647	82 "	101 "
Erie	0.884	76 "	132 "
Ontario	0.955	56 "	20 "

From which it is to be inferred that the interval of time required for an increasing supply to show its effect upon the level of Lake Superior is about 98 days, and for a decreasing supply it is about 91 days; in Lake Erie, the corresponding intervals are 76 days and 132 days respectively; for the other lakes, the intervals are somewhat less.

24. With the data which have been given, it is now possible to show what the practical result will be of an attempt to regulate the level of any lake within any given limits. For illustration, the Commission has selected the regulation of Lake Erie, between the limits 573.7 and 574.7, 1903 levels, by means of a submerged weir and sluice gates, as proposed by the Board of Engineers on Deep Waterways. In this case, the sluice gates cannot be set daily or at frequent intervals, to meet conditions as they arise, because of the difficulty of ascertaining what the true level of the lake is and what its consequent discharge is at any particular time. The irregularity and occasional violence of its oscillations make it necessary to take the average of a considerable number of observations—usually those of a month—to find the true level. The gates can, therefore, be set not oftener than once a month, and then only approximately. It is necessary to fix upon some definite elevation for the stage of the lake at the beginning of each month and then to set the sluice gates to give a discharge which will bring the lake to the level desired at the end of the month. That is to say, it is necessary to estimate the total supply which the lake will receive during the month to come. For regulation between the levels 573.7 and 574.7, the stage values at the beginning of each month should be approximately as follows:

January 1	573.8	May 1	573.9
February 1	573.7	June 1	574.0
March 1	573.7	July 1 to November 1	574.0
April 1	573.8	December 1	573.9

In Table 33 are given the actual supply to Lake Erie, and the supply which would have been estimated if regulating works had been in operation for each month from January, 1890, to December, 1906, inclusive, and their difference. The table gives also the level which the lake would have reached with regulating works, and the difference between the stage reached and the stage desired. The actual supply and the stage are rarely identical with those expected, and in some cases the differences are important. For example, the actual supply in March, 1891, was 37,100 cubic feet per second less than would have been estimated, and in the following month, April, 1891, it was 47,800 cubic feet less than would have been estimated; the stage reached at the end of April, 1891, would have been 573.48, or 5 inches lower than the stage desired. In April, 1892, the supply was 40,200 cubic feet per second, and in the following month it was 29,400 cubic feet per second, more than would have been estimated, and the stage reached at the end of May would have been 574.54, or about 6½ inches higher than the stage desired. In July, 1892, the actual supply was 35,300 cubic feet per second less than would have been estimated. In June, 1893, the actual supply was 39,000 cubic feet per second less than would have been estimated, and in June, 1901, it was 32,300 more. Numerous other instances of important differences will be found in the table. They may occur in any part of the year. They show that it is not possible to foretell the stage under regulation, a month in advance, within 5 or 6 inches; that is to say, that a margin of about 6 inches must be allowed at the upper and lower limits proposed for regulation. If the attempt be made to regulate within a range of one foot, with this margin, there will be no range left for setting the sluice gates, which is absurd. In other words, the regulation of Lake Erie within a range of 1 foot, or between the limits 573.7 and 574.7, is impracticable.

25. It appears, however, from a study of Table 33, that it would have been possible during the period covered by the table, 1890 to 1906, to regulate the level of the lake between the limits 573.31 and 574.74, or within a range of about 18 inches. This period covers the extreme low-water year, 1895, but not an extreme high-water year, like that of 1876. Computations were made to ascertain the effect of regulation between the limits 572.0 and 574.5 in the two extreme years. The results are given in Table 35, and are shown graphically on Plate 21. It is found that the extreme range from high water of 1876 to low water of 1895, which was 3.78 feet, would

under regulation have been reduced to about 2.5 feet. The high levels of 1876 would not have been raised, but the low levels of November and December, 1895, would have been raised 1.38 and 1.37 feet, respectively, and the annual mean level of 1895 would have been raised about 1.07 feet. This would benefit Lake Erie, and is, therefore, worthy of examination.

26. It must not be forgotten that these numbers refer to monthly mean or annual mean stages. It sometimes happens that the stage varies as much as 7 or 8 feet in one day, and more than 2 feet in one hour. Storms raise the water level at Buffalo, several feet higher than normal, and lower it, at Amherstburg, by a like amount; the difference of level between the two ends of the lake in extreme cases having been as great as 15 feet. To control these irregular variations is impossible. It is possible only to regulate the monthly mean stage within the limits of about 2.5 feet. Whether or not it will be expedient to undertake the regulation of Lake Erie between these limits must depend upon the following considerations.

27. Effect Upon Lake Erie. An examination of Plate 21 shows that for a year of excessive supply, such as 1876, the regulation of Lake Erie would not improve navigation. In 1895, a year of deficient supply, the mean level during the eight-month season of navigation would have been raised from 571.31 under natural conditions, to 572.41 under regulated conditions, and navigation would have been improved by an increase of 1.1 feet in the stage. The extreme low stages for the navigation season would have been raised at least 1 foot without appreciable increase in the extreme high stage. This is equivalent to deepening every harbor and channel in Lake Erie by that amount.

28. Effect Upon Lake St. Clair. The increase in the stage of Lake Erie will decrease the mean slope in the Detroit River, and will cause Lake St. Clair to rise, until the slope be so far restored as to give to the discharge through the Detroit River a value equal to the natural discharge. The amount which Lake St. Clair will rise on account of an increase of 1 foot in the stage of Lake Erie, is computed to be 0.61 foot. (See paragraph 121 of the Appendix.)

29. Effect Upon Lake Michigan-Huron. As backwater from Lake Erie raises the level of Lake St. Clair, so backwater from Lake St. Clair raises the level of Lake Michigan-Huron. The effect of an increase of 0.61 foot in the stage

of Lake St. Clair is to raise the level of Lake Michigan-Huron 0.27 foot. (See paragraph 123 of the Appendix.)

30. Effect Upon Lake Ontario, and the St. Lawrence Canals. Any change in the outflow of Lake Erie will change the water levels of Lake Ontario. If the inflow to Ontario is increased the lake level will rise, and with decreased inflow the level will fall. For the extreme years, 1876 and 1895, the effect upon Lake Ontario of the regulation of Lake Erie is shown in Table 36, and on Plate 21. For the high water year, 1876, there would have been but little change; at no time during the year would the regulated stage of Lake Ontario differ from the actual stage more than 1½ inches. In 1895, the low water year, the oscillation would have been increased. The high water of May would have been about 1 inch higher, while the low water of September, October, and November would have been 4.08, 4.46, and 4.00 inches, respectively, lower under regulation than under the natural conditions. To lower the level of Lake Ontario is to lower the St. Lawrence River and to injuriously affect navigation in the St. Lawrence canals. A comparison of the gage records upon Lake Ontario and at these canals shows that a fall of 4.56 inches in the level of Lake Ontario will lower the level in the Galop canals about 4.56 inches, in the Morrisburg canals by about 6.65 inches, and in the Iroquois Canal, Lock 25, by about 7.66 inches. During periods of low-water it would be necessary to diminish the draft of vessels navigating the canals about 7.66 inches, by decreasing their loads.

31. Effect Upon Niagara River. The effect upon Niagara River would not be important. The stage would not fluctuate through any greater range than under natural conditions. During the winter months, more frequent low water would probably occur, in which case the power companies at Niagara Falls would probably have more difficulty in keeping the channels to their intakes free from ice. During the autumn months navigation might be slightly injured by the prolongation of the low-water season, due to the storage in Lake Erie of a part of the natural discharge.

32. Effect Upon the City and Harbor of Buffalo. Low-lying portions of the city of Buffalo and the adjacent territory are subject to overflow both from the lake and from tributary streams, especially Buffalo Creek. Floods from the lake are due to storms blowing from the southwest. During the severe storm of January 20, 1907, Lake Erie rose to 579.45, or 6.49 feet above the mean for that month, or 7.0 feet above the mean of the preceding and following months. Iron fur-

naces were extinguished, a pumping plant was seriously crippled, and much damage was inflicted upon the lands and property in Buffalo adjacent to the lake and to Buffalo Creek. Under regulation, the monthly mean level of the lake upon that occasion would have been about 2½ inches higher than it was and the height of the flood would have been increased by that amount. Floods from Buffalo Creek are now of common occurrence. With a few days of warm weather in the winter, the discharge of the creek becomes so great as to overflow its banks, and the water sometimes floods an area of 1,600 acres, having a population of 10,000. It is stated by the Department of Public Works of Buffalo that a rise of 2 feet in the stages of the lake causes a rise of about 1 foot in Buffalo Creek in the center of the flood district. Most of the floods in Buffalo Creek occur during January, February, and March, when Lake Erie is at its lowest stage. Some of the greatest floods have occurred during the extreme low-water periods, such as those in the winters of 1896, 1898, 1900, and 1902. With the winter level regulated at a height greater than it actually was upon those occasions, the flood height would have been increased, and greater damage would have occurred.

33. Ice Jams. During every winter ice jams form on Horseshoe Reef at the head of Niagara River. The ice in the lake is blown toward the outlet by a southwest wind, and is piled upon the shallow reef, where it forms an ice jam extending from near the bottom to several feet above the surface of the water. In some instances, the bergs have been 20 to 30 feet high. The proposed regulating works, being placed about a mile below Horseshoe Reef, would aggravate this difficulty. The neck of the outlet might become so effectively blocked with ice that the flow of the river would be materially decreased as was the flow of the St. Clair River in the winters of 1901 and 1902. If those conditions should exist, a severe southwesterly storm, such as has occurred on numerous occasions, would inundate the lower part of Buffalo. These ice jams seriously interfere with navigation. The average date of opening navigation in the spring, at Buffalo, is April 9, while at Cleveland, the average date is March 23. The difference of 17 days in the dates of opening the two Lake Erie ports is due to ice jams. It is probable that it would be materially increased by the construction of the regulating works. It is to be observed that the ice jams would make it difficult to maintain the works.

34. Effect Upon the Low-lying Shores of Lake Erie. There are low-lying portions of the shores of Lake Erie where the water is shut out by dykes and where pumping is now required. To raise the level of the lake would increase the amount of such pumping. It is possible, also, that there are points other than Buffalo, where great commercial interests are concentrated, and where local drainage is deficient, but for reasons which will appear presently it has not been considered necessary to make a detailed investigation of every locality.

35. The advantages then of regulating Lake Erie, between the limits 572.0 and 574.5, are that the low-water stages of Lake Erie will be raised about 1 foot; those of Lake St. Clair will be raised about 0.61 foot; and those of Lake Michigan-Huron, about 0.27 foot; without in any case increasing the high water stage.

36. The disadvantages are that the oscillations in Lake Ontario are increased about 5½ inches, and low water is made lower by about 4½ inches; that the depth in the St. Lawrence canals will be diminished by about 7.66 inches; that the city of Buffalo and its southerly suburbs will suffer by increased damage from floods, and from a postponement of the date of opening navigation in the spring.

37. In weighing these advantages and disadvantages, it is to be remembered that the persons who are to benefit by the former are not identical with those who are to suffer from the latter. Those navigating the St. Lawrence canals are not specially concerned with deepening the harbors of Lake Erie; nor are those occupying the low-lying portions of Buffalo sufficiently compensated for the injury to their property by the beneficial effects upon navigation. If the advantages and disadvantages could be equally distributed, we are inclined to think that the former would outweigh the latter, and that the expediency of the undertaking would be a question of cost. As the matter stands, it involves the question of damages to vested rights, which in this case is peculiarly intricate. It is our opinion that the advantages are not of such overwhelming character as to justify the two governments in entering upon that vexatious question, and we therefore recommend that the "regulation" of Lake Erie be not undertaken, meaning thereby the most complete practicable regulation such as can be secured by a dam and sluice gates located at or near Buffalo.

38. It does not follow that nothing can advantageously be done to improve or maintain the level of the lake. It is

possible to raise the level of any lake by simply reducing the size of the outlet. With a reduced cross section, the outlet requires a steeper slope, and the average level of the lake is raised, but the oscillations will go on as before, and the discharge will remain the same. To raise the level of Lake Erie will raise also, but to a less degree, the levels of Lake St. Clair and of Michigan-Huron, and will thus benefit those waters, while it will have no effect upon Lake Ontario or the St. Lawrence River. It would be physically practicable to raise the level many feet, but here again vested rights must be considered, and the amount which the level should be raised is in our judgment limited to that which will not interfere with those rights.

39. It is believed that somewhere in the Niagara River, between Lake Erie and the Falls, a submerged dam may be placed which will greatly benefit the navigation of the waters above without injury to those below and with only minor damages, if any, to the adjoining lands. Without any attempt to "regulate" Lake Erie, the level of the lake may be raised sufficiently to compensate for the damages heretofore inflicted by the Chicago Drainage Canal and other deteriorating influences. To distinguish works of this kind from those designed to "regulate" the lake, they may be called "compensating" works.

40. The upper Niagara River is a valuable safety-valve for the protection of Buffalo from the effects of storms upon Lake Erie, and should not be obstructed by a dam. It is possible that the extreme lower end of the reach, that is, the section just above the Falls, may not be available because of excessive overflow to be caused in the valley of the Welland River. To determine the best site it has been necessary to make additional surveys. These were begun in July, 1909, and are still in progress. After their completion it is our intention to submit a supplementary report upon the subject.

41. In connection with the hydraulic analysis of the general regulation of all the lakes, attention is invited to a discussion of the regulation of Lake Superior, of Lake Michigan-Huron, and of Lake Ontario, which will be found in the Appendix, paragraphs 125-132, 148-155. Without going into details it may be stated in general terms, that, as in the case of Lake Erie, only a very moderate degree of improvement in regulation over what nature provides is practicable in any of the lakes, and that, such as it is, this improvement is obtained at the expense and to the injury of the navigable chan-

nels below. If the level of any lake has been lowered, whether by diversion through the Chicago Drainage Canal or by enlargement of the outlet, the remedy seems to lie in "compensating" rather than in "regulating" works.

42. Attention is invited also to a discussion of the use of Lake Superior as a reservoir, which has been proposed by persons not familiar with the Great Lakes, to compensate for the diversion of water through the Chicago Drainage Canal (see Appendix, paragraphs 133-147). The result of the discussion is to show: 1, that Lake Superior, being naturally one of the greatest and best regulators of flow to be found in the world, maintains a flow in the St. Marys River, its outlet, which is remarkably uniform; 2, that uniformity of flow in that river is essential to the best interests of navigation of the river itself; 3, that during the winter months when navigation is suspended this uniformity of flow is still necessary to maintain the level of Lake Huron, and keep it in condition to maintain in its turn the St. Clair and Detroit Rivers in the spring when navigation opens. It is not in the power of man to improve this uniformity of flow to any important degree. He may disturb it, making it less uniform, by storing water in Lake Superior, but any water withheld at one season would create a deficiency in the lake below, which must be replaced by a equivalent increase of discharge from Lake Superior at another season. This would simply increase the oscillations in the level of the lakes below, that is, would injure them, without compensating in any degree for the diversion of water through the Chicago Drainage Canal.

APPENDIX.

INTERNATIONAL WATERWAYS COMMISSION.
OFFICE OF AMERICAN SECTION,
BUFFALO, N. Y., December 4, 1900.

THE INTERNATIONAL WATERWAYS COMMISSION:

Your committee, which was appointed to investigate the advisability of locating a dam at the outlet of Lake Erie (as proposed by the Board of Engineers on Deep Waterways) and the maintenance and regulation of suitable levels on the other lakes in the Great Lakes system, now has the honor to report upon these subjects. It is hoped that this investigation will be of assistance to the Commission in considering the subjects mentioned above.

THE GREAT LAKES.

1. The Great Lakes, comprising Lakes Superior, Michigan, Huron, Erie, and Ontario, situated between the United States and Canada, differ from the high seas in that the latter have diurnal tides while the former have periodic and seasonal stage cycles. Lake Superior, the largest of these lakes, has a length, from Duluth to Point Iroquois, of 383 miles and a breadth of approximately 160 miles. Its maximum recorded depth is 1012 feet. The outlet of this lake is the St. Marys River. The length of Lake Michigan is approximately 321 miles; its breadth, 118 miles, and its maximum measured depth 870 feet. Lake Huron is about 220 miles long and 101 miles wide, with a maximum measured depth of 750 feet. Lakes Michigan and Huron are connected by the Strait of Mackinac, and their outlet is the St. Clair River. Lake St. Clair is approximately 26 miles long and 24 miles wide; its maximum depth is less than 24 feet, except at the head of the Detroit River, the outlet of the lake. Lake Erie is about 240 miles in length, with a maximum width of 57 miles; its maximum depth, as recorded by the U. S. Lake Survey, is 210 feet. Niagara River is the outlet of this lake. Lake Ontario is about 190 miles long, 57 miles wide, and has a maximum recorded depth of 730 feet. The present natural outlet of this lake, as well as of the entire Great Lakes system, is the St. Lawrence River.

AREAS OF THE SEVERAL LAKES AND WATERSHEDS OF THE GREAT LAKES SYSTEM.

2. The areas of the surfaces of the Great Lakes and their watersheds, as detemined by the United States Lake Survey, are shown in Table 1.

TABLE 1.

LAKE.	Area of Lake Surface in Square Miles.	Drainage Area, Including Lake Surface in Square Miles.	Ratio of Lake to Land Area.
Superior	32,000	76,134	1: 1.37
Michigan	22,336	65,799	1: 1.95
Huron	22,978	72,008	1: 2.13
Michigan-Huron	45,314	137,807	1: 2.04
St. Clair	503	6,194	1: 11.31
Erie	9,968	34,573	1: 2.47
Ontario	7,243	32,980	1: 3.55

Authority: 1906 United States Lake Survey report. (Unpublished).

3. The land area for any watershed is considered as the difference between the total drainage area and the area of the lake surface. The areas of the small lakes and streams are taken as a part of the land area.

4. The ratio of lake to land area is least for Superior and greatest for St. Clair, and increases with each succeeding lake lower in the system, St. Clair excepted.

WATER-LEVEL RECORDS OF THE GREAT LAKES AND THEIR CONNECTING RIVERS.

5. Beginning about 1860 and continuing to date, daily or tri-daily water-level observations have been taken on the several lakes and connecting channels of the Great Lakes. These readings have been reduced to monthly mean stage by determining the average for the month. In 1899, the first self-registering automatic gages, giving a continuous graphical record of the rise and fall of the water, were installed. The water-level records tabulated in this report pertain directly to the stage of the waters of the Great Lakes system. In nearly every instance, they have been placed at the service of the Commission through the Chief of Engineers' reports, or have been obtained from the United States Lake Survey.

6. MARQUETTE. The elevation of the water surface of Lake Superior above mean tide at New York was observed at Superior, Wis., for the period from 1860 to 1871, inclusive, while from 1872 to 1907, inclusive, it was observed at Mar-

quette, Mich. The self-registering gage, located at Marquette, was placed in operation in November, 1902. During the forty-eight years of observations, there were months when no records were taken. For the years 1860 and 1861, missing values have been supplied by adding (algebraically) to the observed reading of the following or preceding month the monthly mean rise or fall of water surface from 1860 to 1871, inclusive. Missing values in the period from 1871 to 1888, inclusive, have been supplied by adding to Sault Ste. Marie, Mich., readings the monthly mean fall from Marquette to Sault Ste. Marie for that period. Missing values for the period from 1889 to 1901, inclusive, have been supplied from the Sault Ste. Marie readings by applying to these readings the monthly mean fall from Marquette to Sault Ste. Marie for that period. The stage of Lake Superior, from 1860 to 1907, inclusive, at Marquette, Mich., and Superior, Wis., is given in Table 2.

7. Sault Ste. Marie. The monthly mean stage of the St. Marys River, the outlet to Lake Superior, was observed at the southwest pier, Sault Ste. Marie, Mich., (above the locks) from November, 1870, to December, 1907, inclusive. Before November, 1899, the readings were taken with a staff gage, but since that time a self-registering gage has been in operation. To make the records complete from January, 1860, to October, 1870, inclusive, the mean monthly fall from 1871 to 1888, inclusive, from Marquette to Sault Ste. Marie, has been subtracted from the corresponding Marquette readings. These monthly mean stages at Sault Ste. Marie (above the locks) are given in Table 3.

8. Milwaukee. The water-level records giving the stage of water of Lake Michigan, from 1860 to 1907, inclusive, were taken at Milwaukee, Wis. The monthly mean elevations of water surface are given in Table 4.

9. Harbor Beach. From September, 1874, to December, 1907, inclusive, the stage of Lake Huron was observed at Harbor Beach, Mich., (formerly Sand Beach). From April, 1901, to December, 1907, inclusive, the stage was recorded by a self-registering gage. The water levels from January, 1860, to August, 1874, inclusive, were derived by the United States Lake Survey, (see page 4105, appendix EEE, annual report of the Chief of Engineers for 1904), as follows: January, 1860, to September, 1864, inclusive, from observations at Point aux Barques; and October, 1864, to August, 1874, inclusive, from observations at Port Austin. These water

levels for Lake Huron stage, from 1860 to 1907, inclusive, are given in Table 5.

10. G. T. R. Water-level observations have been taken near the head of the St. Clair River, at G. T. R. (Grand Trunk Railway) from March, 1899, to December, 1907, inclusive. The computed G. T. R. monthly mean gage readings from January, 1860, to February, 1899, inclusive, were derived from the relation deduced between the monthly mean stage at Harbor Beach and Grand Trunk Railway, from March, 1899, to December, 1904, inclusive. The equations are: for assumed open season, from April to December, (G. T. R.—578)=0.889 (Harbor Beach—578)—0.529, and for the winter season of January, February and March, (G. T. R.—578)=0.889 (Harbor Beach—578)—0.235. The actual observations showed that during the average open season the fall from Harbor Beach to G. T. R. remained practically constant for the same stage, but increased slightly with increasing stages of Lake Huron, while during the winter months the fall decreased materially but also increased slightly with increasing stages of the lake. The G. T. R. gage data are shown in Table 6.

11. St. Clair Flats Canal. In July, 1872, the first authentic records of the stage of Lake St. Clair were taken at the St. Clair Flats Canal. These readings were recorded continuously up to December, 1907, inclusive, with the exception of October, 1877; April and May, 1878; June, 1879, to August, 1881, inclusive; November, 1881, to April, 1882, inclusive; June, September, and October, 1882; December, 1882, to April, 1883, inclusive; January to March, 1902, inclusive; February to April, 1903, inclusive; January, 1906, to October, 1906, inclusive; and August, 1907, to December, 1907, inclusive. From January, 1860, to June, 1872, inclusive, no observations were taken. Values for the missing monthly mean water levels at St. Clair Flats Canal for January, 1861, to July, 1865, inclusive; January, 1866; April and May, 1878, and June, 1879, to August, 1881, inclusive, have been deduced from the monthly means of observations taken simultaneously at St. Clair Flats Canal, the Light-house Depot, Detroit, Mich. (see 1868, United States Lake Survey report in report of the Secretary of War, Fortieth Congress, third session, Vol. 2, 1868-69, p. 985), and Amherstburg, Ont., from which the derived relation between fall from Light-house Depot to Amherstburg, and fall from St. Clair Flats to Amherstburg has been determined. The equation expressing this relation is: (Fall St. Clair Flats to Amherstburg)=1.0357 (Fall Light-house Depot to

Amherstburg)+0.377. Those missing for January, 1868, to March, 1868, inclusive; January, 1869, to March, 1869, inclusive; December, 1869, to March, 1870, inclusive; January and February, 1871; and December, 1871, to March, 1872, inclusive, have been derived from the monthly means of observations taken simultaneously at St. Clair Flats Canal, Old Detroit Waterworks, located at the foot of Orleans Street, Detroit, Mich. (see Forty-ninth regular report of the Board of Water Commissioners to the Common Council of the city of Detroit, 1901), and Amherstburg, Ont., from which has been derived the relation between the fall from St. Clair Flats to Old Detroit Waterworks, and fall from St. Clair Flats to Amherstburg. The derived equation is: (Fall St. Clair Flats to Amherstburg)=0.9378 (Fall Old Detroit Waterworks to Amherstburg)+0.853. Those missing for August, 1865, to December, 1865, inclusive; February, 1866, to December, 1867, inclusive; April, 1868, to December, 1868, inclusive; April, 1869, to November, 1869, inclusive; April, 1870, to December, 1870, inclusive; March, 1871, to November, 1871, inclusive; April, 1872, to June, 1872, inclusive; and October, 1877, have been derived independently from Light-house Depot observations and from Old Detroit Waterworks' records taken at the foot of Orleans Street, Detroit, Mich., as previously explained. The mean of the two derived values has been used for St. Clair Flats. For all months of the year 1860, the St. Clair Flats values (as given on p. 4097, United States Lake Survey report of 1904) have been reduced by 0.67 foot, so as to obtain the original readings taken as the Old Detroit Waterworks, foot of Orleans Street, which were not available. From the original readings thus obtained, new values for stage at St. Clair Flats Canal have been derived by the fall method previously described. The value 0.67 foot represents the mean fall from St. Clair Flats Canal to Old Detroit Waterworks, as deduced on p. 4082 of the United States Lake Survey report for 1904. The derived values for November, 1881, to April, 1882, inclusive; June, September, and October, 1882; and December, 1882, to April, 1883, inclusive, have been obtained by first subtracting 0.48 foot (0.477) from the New Detroit Waterworks' readings and then applying the mean monthly fall from St. Clair Flats to New Detroit Waterworks, as deduced from observations taken at those points from January, 1889, to June, 1901, inclusive. The value referred to above (0.48 foot) represents the discrepancy in the elevation of the zero of the New Detroit Waterworks' gage, as determined about 1878 and during the period from 1893 to

1897. In the forty-ninth regular report of the Board of Water Commissioners of Detroit, it was assumed that the error occurred when the gage was moved and that it had remained at a constant elevation from January, 1878, until 1893. A comparison of these data with those taken simultaneously at St. Clair Flats Canal indicates that the change occurred after May, 1889. Those for January to March, 1902, inclusive; February to April, 1903, inclusive; January to October, 1906, inclusive; and August to December, 1907, inclusive, have been derived from the observations taken at Windmill Point, Lake St. Clair, by applying the mean monthly fall from St. Clair Flats Canal to Windmill Point, as determined from simultaneous observations taken at those points from January, 1897, to July, 1907, inclusive. The monthly mean levels of Lake St. Clair, at St. Clair Flats Canal, are given in Table 7.

12. Windmill Point. Water-level readings have been taken at Windmill Point, near the outlet of Lake St. Clair, by the United States Lake Survey, from 1897 to 1907, inclusive, with the exception of February, 1898, and May and June, 1902. The monthly mean stage values from January, 1860, to December, 1896, inclusive, and for the three missing months mentioned above, have been derived from the St. Clair Flats Canal readings by applying to those values the mean monthly fall from St. Clair Flats Canal to Windmill Point, as determined from simultaneous observations made at those points from January, 1897, to July, 1907, inclusive. The monthly mean values at Windmill Point are given in Table 8.

13. Amherstburg. For several years, commencing with July, 1899, water-surface readings have been taken at the foot of the Detroit River, by which a good relation has been obtained between the water levels at Cleveland, Ohio, and Amherstburg, Ont. The values from January, 1860, to June, 1899, inclusive, and July to December, 1907, inclusive, were derived by applying to the Cleveland, Ohio, readings the mean monthly fall from Amherstburg to Cleveland, as determined from stimultaneous observations at those places from July, 1899, to December, 1904, inclusive. The Amherstburg monthly mean water-surface readings are shown in Table 9.

14. Cleveland. Water-level readings of Lake Erie have been taken at Cleveland, Ohio, from 1860 to 1907, inclusive, with the exception of January, 1877, and October, 1880, to March, 1881, inclusive, which values have been supplied by applying to the monthly mean values for Erie, Pa., the corresponding yearly mean difference of stage between Erie and

Cleveland. The values from January, 1860, to December, 1903, inclusive, have been taken from the United States Lake Survey report for 1904, beginning with p. 4097. Those from January, 1904, to December, 1907, inclusive, have been taken from the United States Lake Survey annual reports. These monthly mean water levels of Lake Erie, at Cleveland, Ohio, are given in Table 10.

15. BUFFALO. All of the water-surface records taken at Buffalo, prior to March, 1887, were accidently destroyed, and values have been derived from Cleveland readings by applying to such readings the mean monthly fall from Cleveland to Buffalo, as derived from simultaneous observations taken at those places from June, 1899, to December, 1906, inclusive. Values for January and February, 1901, and December, 1902, have been supplied in the same way. From 1888 to 1898, inclusive, the monthly means have been derived from the U. S. Lake Survey tables by subtracting 0.1 foot from the records there given. This correction has been determined by a comparison with Cleveland of the mean of the three months, June, July, and August, for each year during this period. From March, 1899, to December, 1907, inclusive, the gage records have been taken with a self-registering automatic gage, located at the Buffalo Breakwater Light-house. The monthly mean elevations of Lake Erie, at Buffalo, N. Y., from 1860 to 1907, inclusive, are given in Table 11.

16. CHARLOTTE. Water-level readings of Lake Ontario have been taken at Charlotte, N. Y., from January, 1860, to October, 1907, inclusive. In 1906, the United States Lake Survey's automatic gage was destroyed and since that time has not been replaced. These monthly mean water-surface elevations of Lake Ontario at Charlotte, N. Y., are given in Table 12.

17. OSWEGO. Water-level observations have been taken at Oswego, N. Y., from 1860 to 1907, inclusive. These water levels give the true elevations of Lake Ontario for that period, with the possible exception of some spring months when the Oswego River is at flood stage. These water-surface elevations of Lake Ontario, at Oswego, N. Y., are given in Table 13.

18. OGDENSBURG. The water-level records of the St. Lawrence River, taken at Ogdensburg, N. Y., are very incomplete. The missing monthly means for Ogdensburg have been derived from Oswego readings by use of the following equation, which has been derived from monthly mean levels at those two places, as deduced from simultaneous observations: (Og-

densburg—240)=0.9426 (Oswego—240)—0.553. The St. Lawrence River water levels, at Ogdensburg, are shown in Table 14.

19. Lock 27. The Canadian Government has observed the stage of water on the sills of the several locks in the St. Lawrence canals for many years. The observations taken at Lock 27, which is located at the head of Galop Rapids in the St. Lawrence River, date from January, 1875, and are complete to December, 1907, inclusive, with the exception of June, 1878, February, 1880, and August and September, 1890, the values for which have been derived from Oswego values, using the following formula: (Lock 27—240)=0.9457(Oswego —240)—1.845. For the period from January, 1860, to December, 1874, inclusive, the water-level values have been derived from Oswego, N. Y., readings according to the above formula, which assumes a mean-fall relation between Oswego and Lock 27 during that period. Table 15 gives the monthly mean water-level records of the St. Lawrence River, at Lock 27, head of Galop Rapids, from 1860 to 1907, inclusive.

20. Lock 24. The water-level readings taken at Lock 24 have been observed from January, 1880, to December, 1907, inclusive, and are complete with the exception of February, 1880, April and May, 1882, and May, 1890. Lock 24 is located at the head of the Morrisburg Canal. This canal was built along a portion of the north shore of the St. Lawrence River, and provides a 14-foot navigable channel around the Rapide Plat. Table 16 gives the monthly water levels at Lock 24, head of Rapide Plat, St. Lawrence River, from January, 1880, to December, 1907, inclusive.

21. Lock 21. The stage observations taken at Lock 21, the upper entrance to the Cornwall Canal and at the head of the Long Sault Rapids in the St. Lawrence River, were begun January, 1870, and are complete to December, 1907, inclusive, with the exception of September, 1882. The monthly mean water-surface readings at Lock 21, Cornwall Canal, head of Long Sault Rapids, St. Lawrence River, are given in Table 17.

22. Plate 1 shows the monthly mean stage of Lakes Superior, Michigan-Huron, St. Clair, Erie, and Ontario from 1860 to 1907, inclusive.

NOMENCLATURE.

23. The following abbreviations and terms are used in this report.

S = Total supply to any lake, in cubic feet per second.

R = Run-off from watershed, in cubic feet per second.

D = Discharge of lake's outlet, in cubic feet per second.

E = Evaporation from lake surface, in cubic feet per second.

P = Precipitation on lake surface, in cubic feet per second.

I = Inflow or transmitted supply from lake above, in cubic feet per second.

L = Local supply, or supply from lake's own drainage area, in cubic feet per second.

s = Storage on lake surface, in cubic feet per second, (positive or negative).

A = Area of lake, in square feet.

h = Depth, in feet, on lake surface, measured from any datum.

t = Time, in seconds, for one-twelfth of a year.

i = Increment, or rate of change of discharge in cubic feet per second per foot change in stage.

u = Coefficient.

g = Acceleration due to gravity, = 32.2 feet per second per second.

b = Width of section, or length of crest of submerged weir in feet.

h_U = Head, in feet, on crest of submerged weir, measured from upstream side.

h_D = Head, in feet, on crest of submerged weir, measured from down-stream side.

F = Fall in stream, expressed in feet.

C = Coefficient.

V = Mean velocity, in feet per second.

k = Theoretical velocity head, in feet, = $V^2 \div 2g$.

h_s = Height of swell, in feet.

d = Mean depth, in feet.

$R_{MAX.}$ = Ratio between the maximum value of mean monthly discharge and the maximum value of mean monthly total supply of any lake.

$T_{MAX.}$ = Time interval in days between the date of the occurrence of the maximum value of mean monthly total supply to any lake and that of the maximum value of mean monthly discharge from that lake.

$T_{MIN.}$ = Time interval in days between the date of the occurrence of the minimum value of mean monthly total supply to any lake and that of the minimum value of mean monthly discharge from that lake.

GENERAL EQUATION FOR STREAM FLOW.

24. The discharge equations of all rivers in the Great Lakes system, with the exception of the St. Marys River, have been derived by use of a submerged-weir formula. Each river bed has been assumed to represent a submerged weir with a broad, flat crest, whose upstream and downstream faces are of considerable length. The location of the submerged weir has been assumed to be at or near the critical cross section, which is generally at the head of the river. The submerged-weir formula is generally recognized in one of the following two forms:

$$D = u\frac{2}{3}b\sqrt{2g}\,(h_U - h_D)^{\frac{3}{2}} + ubh_D\sqrt{2g}\,(h_U - h_D)^{\frac{1}{2}} \quad (1)$$

$$D = u\frac{2}{3}b\sqrt{2g}\,\left(h_U + \frac{h_D}{2}\right)(h_U - h_D)^{\frac{1}{2}} \quad (2)$$

where h_U represents the depth on the average elevation of the crest of the weir, measured from the upstream side,
h_D the depth on the average elevation of the crest of the weir, measured from the downstream side, and
b, the length of the weir crest in feet. The quantity, (h_U—h_D), represents the fall (F) in the stream, or the difference between the upstream and downstream heads. The quantity, $u2/3b\sqrt{2g}$, taken as a whole, represents a variable coefficient (C) which has been derived for each river and is applicable only to that river. This submerged-weir formula reduces to the form,

$$D = CF^{\frac{1}{2}}\left(h_U + \frac{h_D}{2}\right) \quad (3)$$

and was so used in deriving the discharge equations of the several rivers. For every measurement of river discharge, all factors are known with the exception of the coefficient, which has been derived. Knowing the way in which the coefficient for each river varies according to the upstream and downstream head, it is a comparatively simple matter to compute the discharges of the several outlets according to the proper formula. On the St. Clair, Detroit, and St. Lawrence Rivers, the coefficients vary as a function of the upstream and downstream head on the submerged weir. The curve used, showing the manner in which C varies, is the equilateral hyperbola, with its asymptotes parallel to the co-ordinate axes. It is:

$$C = \frac{y}{1 + \frac{x}{h_U}} \quad (4)$$

in which C is the coefficient depending on h_U or h_D, the upstream or downstream head, respectively.
x and y are constants, which represent the distance of the asymptotes from the y and x axes, respectively.
For convenience in deriving the unknown values, this hyperbolic equation has been transformed into a straight-line equation by dividing by y, which gives

$$C = \frac{1}{\frac{1}{y} + \frac{x}{yh_v}} \qquad (5)$$

and then taking the reciprocal of each member:

$$\frac{1}{C} = \frac{1}{y} + \frac{x}{y}\left(\frac{1}{h_v}\right) \qquad (6)$$

DISCHARGE OF ST. MARYS RIVER, OUTLET TO LAKE SUPERIOR.

25. The Marys River, from Point Iroquois, in Lake Superior, to the head of the United States Ship Canal, at Sault Ste. Marie, Mich., is a wide stream with comparatively little slope, there being about two-tenths of a foot fall in this distance. At the latter location, rapids (about one-half a mile in length) connect the upper and lower St. Marys River. The submerged weir of rock at the head of these rapids controls the discharge of water from Lake Superior, and any change in this submerged weir would cause a change in the volume of discharge for the same stage. Any auxiliary channel connecting with the pool immediately above the weir would increase the river discharge for the same stage by the volume thus diverted. During the epoch, 1860 to 1907, inclusive, the regimen of the St. Marys River, above the rapids, was changed on several occasions. In 1887 and 1888, the International Bridge across the St. Marys Rapids was constructed. Prior to that time, the river discharged at the bridge site through four channels, viz., the main rapids and three small streams situated between the islands lying adjacent to the north shore. The building of the bridge piers and approaches and the filling in of portions of the three small streams (called *a*, *b*, and *c*) on the north side of the main channel reduced the effective area at this critical discharge cross section so that the flow of the St. Marys River was materially decreased.

26. In 1889, the Canadian Water Power Company (now the Lake Superior Power Company) commenced work on a power plant and used for its canal the northerly of the three small streams (*c*) previously mentioned. The flow therein was practically stopped until the latter part of 1895, when this power plant was opened. During the year 1892, the Edison Sault Electric Light & Power Company (now the Chandler-Dunbar Water Power Company) built a dyke from the second pier on the American side of the International Bridge, parallel to the shore, for a distance of about 1,500

feet down the stream. The area inclosed by the American shore and this dyke is used as a forebay by the power company, practically shutting off from the main channel the flow through these two spans. By December, 1892, the flow of the river had been restricted by the building of the piers and approaches to the International Bridge, the shutting off of spans 1 and 2 from the main channel on the American side, and the closing of stream *c* on the Canadian side. Beginning in December, 1895, the Lake Superior Power Company started the operation of its plant on a large scale, using water at the rate of approximately 3800 cubic feet per second. This power plant has been in continuous operation since then, with the exception of February and March, 1896, and has gradually increased the quantity of water used until it now reaches about 6000 cubic feet per second. The use of water by the American and Canadian locks has also increased from time to time until it now amounts to an average flow of about 600 cubic feet per second. In 1901, the Michigan Lake Superior Power Company started work on the construction of a compensating works in the rapids of the St. Marys River, about 300 feet above the International Bridge. These works practically shut off the entire flow through spans 9 and 10, the first two spans on the Canadian side of the river. In January, 1905, the Michigan Lake Superior Power Company began to divert water through its canal, using about 8500 cubic feet per second at that time.

27. DISCHARGE MEASUREMENTS. During the winter of 1896, discharge measurements of the St. Marys River were taken by the United States Government at Spry's Dock Section, located about a mile below the St. Marys Rapids. The discharge equation deduced from these observations, modified for the various efflux conditions, has been the governing factor for the determination of the outflow of Lake Superior from January, 1860, to September, 1901, inclusive. The derived equation is:

$$D_{RIVER}=18826\ (\text{Southwest Pier Gage}-600)+37060. \quad (7)$$

See 1906 United States Lake Survey report (unpublished).

28. The Southwest Pier Gage is located at the southwest pier above the American locks at Sault Ste. Marie, Mich. At the time that these measurements were taken, the Chandler-Dunbar Water Power Company was using 1065 cubic feet of water per second through its works; streams *a* and *b* on the north side of the main channel were still open, and the Lake Superior Power Company's plant was closed.

29. In 1902, the United States Lake Survey measured the flow through the St. Marys Rapids at the International Bridge, which connects Sault Ste. Marie, Mich., with Sault Ste. Marie, Ont. The discharge equation derived from these observations gives the flow through the rapids after spans 9 and 10 (the first two spans on the Canadian side) were closed by the construction of the compensating works of the Michigan Lake Superior Power Company. It is:

$D_{RAPIDS} = 15540$ (Southwest Pier Gage—600) + 30510. (8)

30. During February and March, 1905, observations of the flow in the St. Marys River were taken at "Section Brewery," located about 2000 feet below the Spry's Dock Section. The discharge equation derived from these measurements is:

$D_{RIVER} = 18484$ (Southwest Pier Gage — 600) + 41829. (9)

This formula gives the total flow of the river, while that derived from the 1902 measurements gives only the flow through the St. Marys Rapids.

31. ST. MARYS RIVER DISCHARGE FORMULAE, AS USED FOR THE DIFFERENT EFFLUX CONDITIONS. The discharge formula governing the first period, 1860-1888, inclusive, was derived from the measurements made in 1896 and 1902 (the fifth and tenth periods of efflux) in conjunction with hydraulic data taken at the International Bridge Section in 1901 and 1902. The mean stage of the St. Marys River at the Southwest Pier (above the locks), Sault Ste. Marie, Mich., from 1871 to 1905, inclusive, was 601.86 feet above mean tide at New York. The 1896 discharge measurements give: $D_{RIVER} = 18826$ (Southwest Pier Gage — 600) + 37060. The discharge of the river at mean stage was 72076 cubic feet per second. Deducting from this value 1065 cubic feet per second (the amount of water used by the Chandler-Dunbar Water Power Company) and 1798 cubic feet per second (the discharge of two small streams on the north side of the rapids) gives the flow through the main channel of the St. Marys Rapids as 69200 cubic feet per second. From the vertical and transverse percentage velocity curves deduced from observations made at the Bridge Section, for spans 3-10, inclusive, in 1901, and for spans 3-8, inclusive, in 1902, the ratio of flow of the entire cross section to that for any partial section has been determined. These curves show the modification in the transverse velocity curve due to the construction, by the Michigan Lake Superior Power Company, of the compensating works located about 300 feet above the bridge. With these data, the transverse percentage velocity curve at the International Bridge Section, for the first period, has been constructed for the entire main channel,

which included the channels for spans 1 and 2 of the bridge, next the American shore. This curve has been integrated and its mean ordinate, or mean percentage velocity, computed. The product of this value and the mean velocity of the rapid's flow at mean river stage under the 1896 conditions, or during the fifth period of efflux, gives the mean velocity for the main channel under the original conditions, or for the first period of efflux. The product of the mean velocity and the area of the cross section before the bridge was built gives the discharge of the main channel for mean river stage. The equations giving the actual computations are:

$$D_1 = A_1 \left(\frac{D_5}{A_5} \times \text{mean percentage } V_1\right) = A_1 V_1 \qquad (10)$$

$$= 13690\left(\frac{69200}{10650} \times 0.925\right) = 13690 \times 6.01 = 82280$$

cubic feet per second, discharge of main channel for mean river stage under original conditions.

32. With the volume of flow known for mean river stage, the only remaining step is to derive the increment of discharge per foot change in stage. In deriving this increment, use has been made of Bernouilli's theorem applied to open channels with steady flow, expressed as follows:

$$\text{Friction head} = F + \frac{V^2_{\text{UPSTREAM}}}{2g} - \frac{V^2_{\text{DOWNSTREAM}}}{2g} \qquad (11)$$

33. It has been assumed that the friction heads before and after the rise were proportional to the squares of the respective velocities at the Bridge Section. The two cross sections used are: The upper one, located nearly opposite the Southwest Pier Gage, and the lower one, at the International Bridge. Under original conditions, the areas of the upper and lower cross sections were 46260 and 13690 square feet, respectively, and the width were 3400 and 2383 feet, respectively, at 601.86 feet, the mean river stage at Southwest Pier Gage. According to formula 10, the discharge of the river at this stage was 82280 cubic feet per second. The corresponding mean water surface at the Bridge Section was 600.56 feet. Substituting these values in the preceding formula gives: Friction head before rise=1.30+0.049—0.562=0.787 foot. Actual measurements taken under the conditions existing for the fifth and tenth periods show that a rise of 1 foot at Southwest Pier Gage for mean river stage caused a rise of 0.636 and 0.592 foot at the bridge, respectively. These are the values for rise before and after the

compensating works had been constructed. The mean of the above values (0.614 foot) has been used as the assumed rise under original conditions, since the relation appeared to be nearly constant for two radically different discharge periods. After a rise of 1 foot at the upstream section, the mean velocity became $\frac{D}{49660}$ feet per second, and the corresponding velocity head was $\frac{(\frac{D}{49660})^2}{2g}$. For the rise of 0.614 feet at the downstream section, the mean velocity became $\frac{D}{15150}$ feet per second, and the corresponding velocity head was $\frac{(\frac{D}{15150})^2}{2g}$. The potential head after rise was: $F=1.30+1.00-0.614=1.686$ feet. Substituting the new values in Bernouilli's formula gives: Friction head after rise $= 1.686+ \frac{(\frac{D}{49660})^2}{2g} - \frac{(\frac{D}{15150})^2}{2g}$. Under the previous assumption that the friction heads before and after the rise were proportional to the square velocities, we have:

$$0.787 : 1.686 + \frac{(\frac{D}{49660})^2}{2g} - \frac{(\frac{D}{15150})^2}{2g} :: 6.01^2 : (\frac{D}{15150})^2 \qquad (12)$$

whence D=103840 cubic feet per second. This value represents the discharge through the main channel at 1 foot above mean river stage, 601.86. The difference between this discharge value and 82280, the discharge for mean stage, is 21560 cubic feet per second, the increment of discharge for 1 foot rise above mean stage. This method was also used for the determination of the increment for one foot below mean stage, which gave 20720. The mean of 21560 and 20720, viz., 21140 cubic feet per second, has been used as the increment of discharge.

34. The discharge formula governing the flow through the main channel for the period is as follows:

$D_{1\ \text{MAIN CHANNEL}}=21140$ (Sou't west Pier Gage—601.86)+ 82280. (13)

35. The two small streams (*a* and *b*) situated on the north side of the main channel had a flow of 1800 cubic feet per second at mean river stage, with an estimated increment of discharge per foot rise of 950 cubic feet per second. The

third small stream (*c*) situated also on the north side of the main channel had an estimated flow of 1800 cubic feet per second at mean river stage, with an estimated increment of discharge per foot rise of 950 cubic feet per second. By combining the above results, the discharge formula of the St. Marys River for the original conditions, or first period, (January, 1860, to November, 1888, inclusive), before any alterations had occurred in the outlet to Lake Superior above the St. Marys Rapids, is:

$D_1 = 23040$ (Southwest Pier Gage — 601.86) + 85880. (14)

36. The construction of any engineering structure necessarily takes time; so, in the building of the piers and approaches for the International Bridge, some time elapsed before the completion of the substructure. It is assumed that original conditions prevailed to December 1, 1888, after which the piers and approaches for the International Bridge are considered as having been completed, and stream *c*, adjacent to the north shore, as having been closed. This date marks the beginning of the second period, which is assumed to continue to December, 1892, inclusive. The discharge formula governing the flow through the main channel for this efflux condition has been computed in the same way as that for the first period. It is:

$D_{2\ \text{MAIN CHANNEL}} = 19080$ (Southwest Pier Gage—601.86)+ 77200. (15)

37. Two small streams (*a* and *b*) situated on the north side of the main channel were still flowing, as in the first period. Combining the results of the flow through the main channel and streams *a* and *b* gives the total flow in the St. Marys River for the second period as:

$D_2 = 20030$ (Southwest Pier Gage—601.86)+79000. (16)

38. For the third period, January, 1893, to November, 1895, inclusive, the efflux condition was the same as that for February and March, 1896, when the discharge measurements were taken. It is assumed that the Chandler-Dunbar Water Power Company closed spans 1 and 2, on the American end of the International Bridge, at the beginning of this period. The volume of water used by them was estimated to be about 1065 cubic feet per second. Streams *a* and *b* were still flowing. The equation of discharge for St. Marys River for the third efflux condition is:

$D_3 = 18826$ (Southwest Pier Gage—600)+37060. (17)

39. In December, 1895, the beginning of the fourth period, the Lake Superior Power Company began using water on a large scale, estimated by the chief engineer of the Lake

Superior Power Company at 3800 cubic feet per second. The Chandler-Dunbar Water Power Company is assumed to have been still using 1065 cubic feet per second. Streams *a* and *b* were still flowing. The discharge equation for the fourth period, from December, 1895, to January, 1896, inclusive, is:

D_4=18826 (Southwest Pier Gage—600)+40860. (18)

40. The fifth epoch, February and March, 1896, marks the date of the first discharge measurements of the St. Marys River used in this report. The discharge formula for the river flow is:

D_5=18826 (Southwest Pier Gage—600)+37060. (19)

41. For the sixth period, April, 1896, to December, 1897, inclusive, the auxiliary flow is estimated at 3500 cubic feet per second through the works of the Lake Superior Power Company. Streams *a* and *b* were still open. The Chandler-Dunbar Water Power Company was using approximately 1065 cubic feet per second. The three latter are included in the river discharge formula as derived from observations made in February and March, 1896. The discharge equation of the St. Marys River for this period is:

D_6=18826 (Southwest Pier Gage—600)+40560. (20)

42. For the seventh period, January, 1898, to March, 1899, inclusive, 4000 cubic feet per second is estimated as the side flow through the works of the Lake Superior Power Company. Streams *a* and *b* were still flowing. The Chandler-Dunbar Water Power Company is estimated to have been still using about 1065 cubic feet per second. The discharge through the locks for this period and previous thereto has not been incorporated in the discharge equations, owing to the fact that it is considered to have been, comparatively, a small quantity. The discharge equation giving the flow of the St. Marys River for this period is:

D_7=18826 (Southwest Pier Gage—600)+41060. (21)

43. For the eighth period, April, 1899, to December, 1899, inclusive, the side flow through the works of the Lake Superior Power Company is estimated at 4000 cubic feet per second. Streams *a* and *b* were still flowing. The Chandler-Dunbar Water Power Company is assumed to have increased its flow at the beginning of the period from 1065 cubic feet per second to 1400 cubic feet per second. It is estimated that the American and Canadian locks were using at that time an average flow of 600 cubic feet per second. By combining the above data, the net side flow, other than that at the time of the 1896 discharge measurements,=4000+(1400—1065)+600=4935 cubic feet per second, (4940 used). The discharge

formula for the St. Marys River for this period is:

$D_9 = 18826$ (Southwest Pier Gage $- 600) + 42000$. (22)

44. For the ninth period, January, 1900, to September, 1901, inclusive, streams *a* and *b* are assumed to have been closed at the beginning of the epoch. The shutting of these two channels decreased the increment of discharge per foot rise by 950 cubic feet per second, or to 17880, but did not change the total discharge for the main channel at stage 600 on account of the discharge of streams *a* and *b* being approximately zero at this stage. The side flow through the works of the Lake Superior Power Company is estimated to have been 5000 cubic feet per second. The Chandler-Dunbar Water Power Company and the American and Canadian locks are assumed to have been using 1400 and 600 cubic feet per second, respectively. By combining the above data, the net side flow of the river, other than that at the time of the 1896 measurements, was: $5000 + (1400 - 1065) + 600 = 5935$ cubic feet per second, (5940 used). The discharge formula for the St. Marys River for this period is:

$D_9 = 17880$ (Southwest Pier Gage—600)$+43000$. (23)

45. For the tenth period, October, 1901, to December, 1904, inclusive, the discharge formula derived from the measurements taken at the International Bridge in 1902, after the compensating works had been constructed by the Michigan Lake Superior Power Company, is:

$D_{10\ \text{MAIN CHANNEL}} = 15540$ (Southwest Pier Gage—600)$+ 30510$. (24)

46. This equation represents the flow through the St. Marys Rapids and does not take into account the flow through the Chandler-Dunbar Water Power Company's forebay and plant. Previous to this period, the quantity of water used by the Chandler-Dunbar Water Power Company is considered directly in the discharge equation. The side flow through the works of the Lake Superior Power Company is estimated to have been 5000 cubic feet per second. The Chandler-Dunbar Water Power Company and the American and Canadian locks are estimated to have been using about 1400 cubic feet per second and 600 cubic feet per second respectively. The discharge formula of the St. Marys River, used for this efflux condition, is:

$D_{10} = 15540$ (Southwest Pier Gage—600)$+37510$. (25)

47. For the eleventh period, January, 1905, to December, 1907, inclusive, the discharge formula depends on discharge measurements made by the United States Lake Survey in February and March, 1905, at "Section Brewery," located

about 2000 feet below Spry's Dock Section, which was situated opposite the power house belonging to the Michigan Lake Superior Power Company. During this period, the side flow through the works of the Lake Superior Power Company, the Michigan Lake Superior Power Company, the Chandler-Dunbar Water Power Company, and the American and Canadian locks is estimated at 6000, 8500, 1400, and 600 cubic feet per second, respectively. The discharge formula giving the total flow of the river for this period, based on the 1905 measurements, is:

D_{11}=18484 (Southwest Pier Gage—600)+41830. (26)

48. It has been noted that the discharge formula for efflux periods 10 and 11 show a difference in the increment of discharge of 2944 cubic feet per second for substantially the same conditions, the only known change in the regimen being an assumed constant diversion of 8500 cubic feet per second through the canal of the Michigan Lake Superior Power Company. This difference in increment is probably due in part to greater leakage at high stage through the dam of the Chandler-Dunbar Water Power Company.

49. The following table gives a summary of the discharge equations for the St. Marys River for the several efflux periods:

TABLE 18.

SUMMARY OF ST. MARYS RIVER DISCHARGE EQUATIONS FOR THE DIFFERENT EFFLUX CONDITIONS.

No. of Period.	Length of Period.	Discharge Equation, St. Marys River.
1	Jan. 1860—Nov. 1888	D_1 = 23040 (Southwest Pier Gage — 601.86)+33330
2	Dec. 1888—Dec. 1892	D_2 = 20030 (Southwest Pier Gage — 601.86)+79000
3	Jan. 1893—Nov. 1895	D_3 = 18426 (Southwest Pier Gage — 600.00)+37000
4	Dec. 1895—Jan. 1896	D_4 = 18526 (Southwest Pier Gage — 600.00)+36800
5	Feb. 1896—Mar. 1896	D_5 = 18826 (Southwest Pier Gage — 600.00)+37080
6	Apr. 1896—Dec. 1897	D_6 = 18826 (Southwest Pier Gage — 600.00)+40500
7	Jan. 1898—Mar. 1899	D_7 = 18826 (Southwest Pier Gage — 600.00)+41000
8	Apr. 1899—Dec. 1899	D_8 = 18826 (Southwest Pier Gage — 600.00)+42000
9	Jan. 1900—Sep. 1901	D_9 = 17880 (Southwest Pier Gage — 600.00)+43000
10	Oct. 1901—Dec. 1904	D_{10} = 15540 (Southwest Pier Gage — 600.00)+37510
11	Jan. 1905—Dec. 1907	D_{11} = 18484 (Southwest Pier Gage — 600.00)+41830

Southwest Pier Gage gives the elevation of the water surface of St. Marys River at Southwest Pier, above the locks, Sault Ste. Marie, Mich., above mean tide at New York.

50. The monthly mean discharge values of the St. Marys River, from January, 1860, to December, 1907, inclusive, are given in Table 19.

51. Probable Effect Upon Mean Level of Lake Superior of Obstructions in St. Marys River at Head of Rapids. Any obstruction placed in a river at or near its critical or con-

trolling discharge section changes the volume of flow and affects the level of the lake above and also the levels of those below. The construction of the piers and approaches of the International Bridge changed the discharge of the river and raised the mean level of Lake Superior. The shutting off of spans 1 and 2 on the American side, from the main channel, by the Chandler-Dunbar Water Power Company, and the construction of the compensating works by the Michigan Lake Superior Power Company have also had their effect on the level of Lake Superior and the lower lakes. The ultimate effect of these obstructions placed in the main channel has been derived for mean river stage on the assumption that no diversions have been made by the Lake Superior Power Company or the Michigan Lake Superior Power Company. This maximum effect on lake levels has not entirely taken place, owing to these diversions by the said power companies. In treating this subject, use has been made of the incomplete-weir formula, river-discharge increments and river-gage relations. The discharge through the main channel of the St. Marys Rapids for the third to ninth periods, inclusive, for mean river stage at Southwest Pier Gage, (1871 to 1905, inclusive,) 601.86, has been previously computed as 69200 cubic feet per second. The corresponding measured mean water surface at the International Bridge Section during this period of flow was 600.61. In 1902, after the compensating works of the Michigan Lake Superior Power Company were built, practically closing spans 9 and 10, the mean water surface of this section was measured as 600.98 for the same discharge, 69200 cubic feet per second. This rise of 0.37 foot in the water surface represents the swell, h_s, at the International Bridge Section, due to the shutting off by the compensating works of the two spans on the Canadian side of the rapids. These actual measurements afford a means for determining an experimental value of u in the incomplete-weir formula.

$$D = ub\sqrt{2g}\left\{\frac{2}{3}\left[(h_s+k)^{\frac{3}{2}}-k^{\frac{3}{2}}\right]+d\,(h_s+k)^{\frac{1}{2}}\right\}. \qquad (27)$$

where D=69200 cubic feet per second, the discharge through the St. Marys Rapids, in third to ninth periods, inclusive, with mean water surface at International Bridge of 600.61, and in tenth period with mean water surface of 600.98, b_A= 1511 feet, width of channel after obstruction by compensating works,

2g=64.4 feet per second per second,

h_s=height of swell, in feet.

$k = \frac{V^2}{2g} = \frac{(D/A_B)^2}{2g} =$ 0.655 foot=theoretical velocity head previous to placing of obstruction, and where A_B is area of cross section of main channel before compensating works were built=10650 square feet.

$d = \frac{A_B}{b_B} = \frac{10650}{1794} =$ 5.937 feet=mean depth previous to construction of works, where b_B is width of channel in third to ninth periods, inclusive. Substituting these values in the above equation and solving gives a value for u of 0.899. The building of the piers and approaches of the International Bridge, according to computations, reduced the discharge through the main channel from 82280 to 77200 cubic feet per second, decreased the channel width from 2383 to 2232 feet, and changed the cross-sectional area from 13690 to 12490 square feet. Substituting these values in the incomplete-weir formula and using the experimental value of u (0.90) gives the swell, h_s, at the bridge site, due to the construction of the piers and approaches, as 0.183 foot. The corresponding rise at Southwest Pier was 0.298 foot. This latter value represents the estimated rise in mean lake level caused by the building of the International Bridge. About four years after the International Bridge was built, the Chandler-Dunbar Water Power Company shut off spans 1 and 2, on the American side, from the main channel. This obstruction reduced still more the mean discharge through the main channel. Using the incomplete-weir formula.

$$D = ub\sqrt{2g}\left\{\frac{2}{3}\left[(h_s+k)^{\frac{3}{2}}-k^{\frac{3}{2}}\right]+d(h_s+k)^{\frac{1}{2}}\right\}$$

for determining the effect of building the bridge piers and approaches and closing spans 1 and 2, where D = 82280 cubic feet per second, discharge at mean river level, 601.86, under original conditions,

u=0.90, experimental coefficient for present case,

b_A=1794 feet, width of channel after obstructions were built,

2g=64.4 feet per second per second,

$k = \frac{V^2}{2g} = \frac{(D/A_B)^2}{2g} =$ 0.562 feet, theoretical velocity head previous to placing of obstructions, where A_B is area of cross section of main channel before structures were placed =13690 square feet.

$d = \frac{A_B}{b_B}$ =5.745 feet=mean depth before structures were placed, whereb_B=2383 feet,
and solving for h_s gives 0.496 foot as the swell at the Bridge Section due to the construction of these works. The discharge formula for the flow through the main channel of the rapids, after the bridge piers and approaches were built and spans 1 and 2 were closed, according to 1896 measurements, is: $D_{RAPIDS\ 3-9}$=17880 (Southwest Pier Gage—600.00) +35995, while that after the compensating works were built, according to the 1902 measurements, is: $D_{RAPIDS\ 10}$=15540 (Southwest Pier Gage—600.00)+30510. The increment at Southwest Pier Gage, as determined in 1896 and 1902, is 17880 and 15540, respectively, while that at the Bridge Section for the 1896 conditions was unknown, and for 1902 was 22600. In order to determine the increment at the bridge, under the 1896 conditions, the assumption has been made that the increments of discharge per foot rise under the same efflux conditions are directly proportional for various points in a stream. This proportion is; Increment Southwest $Pier_{10}$: increment Southwest Pier $_{3-9}$ :: increment $Bridge_{10}$: increment $Bridge_{3-9}$ or, inserting values, 15540 : 17880 :: 22600 :X. Solving: X=26000. The difference between the discharge through the main channel in the rapids for the first period and the third-ninth period is 82280—69200=13080 cubic feet per second. This quantity represents the volume of water cut off by the construction of the bridge piers and approaches and closing of spans 1 and 2. Since 1 foot rise at the bridge, under original conditions, is equivalent to an increase in discharge of 26000, then the swell caused by these obstructions, involving a reduction in discharge of 13080 cubic feet per second, is =0.503 foot. The swell at the bridge, due to the building of the piers and approaches for the International Bridge, the shutting off of spans 1 and 2 by the Chandler-Dunbar Water Power Company, and the closing of spans 9 and 10 by the construction of the compensating works, computed by the incomplete-weir formula, is 0.817 foot. Subtracting 0.37 foot, the actual measured swell due to the building of the Compensating works, gives 0.447 foot as the swell at the Bridge Section due to the building of the piers and approaches of the International Bridge and the shutting off of spans 1 and 2.

52. Summarizing: The swell at the Bridge Section, due to the construction of the piers and approaches and shutting off of spans 1 and 2, is:

Incomplete weir, (direct)	0.496 foot
Increment	.503 foot
Incomplete weir, (indirect) 0.817 — 0.370	.447 foot
Mean swell	.482 foot

53. The above value represents the swell at the bridge due to these obstructions, but it does not represent the true effect on the St. Marys River at Southwest Pier. Since the increment of discharge at Southwest Pier is 17880, the swell at that point, due to decreasing the discharge through the rapids by 13080, is $\frac{13080}{17880}$ =0.732 foot. By water-surface relations between Southwest Pier and mean water surface at Bridge, it is found that for mean river stage (601.86) at Southwest Pier, the corresponding mean water surface at Bridge is 600.613. Adding 0.482 foot, the mean swell at the bridge due to the construction of the piers and approaches and shutting off the spans 1 and 2, gives 601.095 as the new mean water surface. The gage readings as Southwest Pier, corresponding to this mean water surface at the bridge, is 602.645. The difference between 602.645 and 601.86 is 0.785, the swell due to building these obstructions.

54. Summarizing: The swell at Southwest Pier, due to building the piers and approaches for the International Bridge and shutting off of spans 1 and 2, is:

Increment method	0.732 foot
Gage relations	.785 foot
Mean	.758 foot

55. During the period immediately following the building of the compensating works, the mean water surface at the Bridge Section was 600.54 for mean river stage. The rapid's discharge, corresponding to this gage height, was 59300 cubic feet per second. The difference between the mean rapid's discharge before and after the building of these works is computed to be 69200—59300=9900 cubic feet per second. The increment of discharge at the bridge, as determined by measurement, was 22600. From these data, the swell at the bridge is computed to be $\frac{9900}{22600}$ =0.439 foot. Actual measurements taken before and after the compensating works were built give the swell at the bridge as 0.37 foot.

56. Summarizing: The swell at the Bridge Section, due to the construction of the compensating works, is:

Increment (direct)	0.439 foot
Actual measurement	.370 foot
Incomplete weir (indirect, 0.817 — 0.482)	.335 foot
Mean	.381 foot

57. The swell at the Southwest Pier for this period, computed by the increment method, is =0.638 foot, while by gage relations it was 0.648 foot. The mean of these two values gives 0.643 foot as the rise in the mean river stage at the southwest pier, due to the compensating works.

58. SUMMARY. The mean stage of St. Marys River at the southwest pier, from 1871 to 1905, inclusive, is 601.86. The effect of the building of the piers and approaches to the International Bridge and the shutting off of spans 1 and 2 on the American shore by the Chandler-Dunbar Water Power Company was to raise the mean river level at the Southwest Pier 0.758 foot, or to an elevation of 602.618. The effect of the construction of the compensating works on the mean river level at Southwest Pier was to raise it 0.643 foot, or to a new mean river stage of 603.261. The mean water surface at the International Bridge, after the compensating works were built, corresponding to 603.261 at Southwest Pier, was 601.423 feet. Subtracting from this value the swell at the bridge, due to the compensating works namely, 0.381 foot, gives the mean water surface at the bridge, before the compensating works were built, as 601.042. Subtracting from this new value 0.482 foot, the swell at the Bridge Section due to the construction of the piers and approaches to the International Bridge, and the shutting off of spans 1 and 2 from the main channel, gives 600.56 as the original mean water surface at the Bridge Section. The effect of placing obstructions in the St. Marys River at or near the International Bridge site has been to raise the mean level of the river at the bridge and Southwest Pier, and also the mean level of Lake Superior. If no diversions from the upper river had occurred, the ultimate rise in the mean level of the St. Marys River and Lake Superior would have been approximately 1.40 feet; but, owing to diversions having taken place, this rise has been diminished.

ST. CLAIR RIVER DISCHARGE.

59. During the period from April, 1899, to September, 1902, inclusive, the United States Lake Survey measured the discharge of the St. Clair River, the outlet to Lake Huron,

in the vicinity of Port Huron, Mich. These measurements have been used in deriving a formula for the flow of this river in terms of G. T. R. and Dry Dock gage heights. The elevation of the crest of the submerged weir has been assumed at 543 feet above mean sea level. The St. Clair River discharge formula, as derived, is:

$$D = \left(\frac{C_{G.T.R.} + C_{D.D.}}{2}\right) F^{\frac{1}{2}} \left(h_U + \frac{h_D}{2}\right) \qquad (28)$$

in which the coefficients depending on the stage at G. T. R. and Dry Dock, derived from the discharge measurements, are:

$$C_{G.T.R.} = \frac{2700.316}{\frac{62.872}{h_U} - 1}, \text{ and } C_{D.D.} = \frac{2766.21}{\frac{61.982}{h_D} - 1}, \text{ respectively.}$$

60. This discharge equation of the St. Clair River, depending on the gage readings at G. T. R. and Dry Docks, has been transformed to one depending on G. T. R. and St. Clair Flats, on account of the long series of readings taken at the St. Clair Flats Canal. In order to substitute the St. Clair Flats Canal readings for Dry Dock readings in the discharge formula, the following equation was used: (Fall, G. T. R. to St. Clair Flats Canal)=7.4482 (Fall G. T. R. to Dry Dock)—1.9657. The St. Clair River discharge formula, as transformed, is:

$$D = \frac{C_{G.T.R.} + C_{ST.\ CLAIR\ FLATS\ CANAL}}{2} F^{\frac{1}{2}} \left(h_U + \frac{h_D}{2}\right). \qquad (29)$$

The coefficients derived in this transformed equation are:

$$C_{G.T.R.} = \frac{1308.339}{\frac{64.674}{h_U} - 1}, \text{ and } C_{ST.\ CLAIR\ FLATS\ CANAL} = \frac{1445.118}{\frac{59.123}{h_D} - 1}.$$

61. This last equation, expressed in terms of St. Clair Flats and G. T. R., has been used to compute the mean discharges of St. Clair River from 1860 to 1907, inclusive.

62. In 1900, the Chicago Drainage Canal began deverting water from Lake Michigan. The quantity used from 1900 to June, 1904, inclusive, has been computed from data furnished the Commission by the United States Engineer Office at Chicago. The flow through the canal for the last half of the year 1904, and 1905, 1906, and 1907, has been assumed to be the quantity authorized in the permit of the Secretary of War.

DETROIT RIVER DISCHARGE.

63. The Detroit River discharge equation has been derived from measurements taken at Fort Wayne, Mich., by the United States Lake Survey during the summers of 1901 and 1902. The elevation of the crest of the weir is assumed as 540 feet above mean sea level. A part of these observations were rejected owing to the fluctuation in the level of water at Amherstburg during the discharge measurement. The remaining discharges were used in determining the discharge equation. The discharge formula, as derived, is:

$$D_{\text{DETROIT}} = \frac{C_{\text{W.PT.}} + C_{\text{AM H.}}}{2} F^{\frac{1}{2}} \left(h_U + \frac{h_D}{2}\right). \qquad (30)$$

in which $C_{\text{W.PT.}}$ for the upstream head at Windmill Point $= \frac{11.745}{\frac{52.248}{h_U} - 1}$,

$C_{\text{AMH.}}$ for the downstream head at Amherstburg $= \frac{20.529}{\frac{60.083}{h_D} - 1}$,

F = fall, Windmill Point to Amherstburg,

h_U = upstream head on crest of submerged weir, determined by Windmill Point gage heights,

h_D = downstream head on crest of submerged weir, determined by Amherstburg gage heights.

64. Owing to the lack of sufficient observations, no winter discharge formula have been derived for the Detroit or St. Clair Rivers. It is, undoubtedly, true that for the same slope the discharge is less with an ice covering than without one, on account of the increased friction.

Ice gorges occur in the St. Clair and Detroit rivers nearly every winter, creating an abnormal slope in the river that is gorged. Under such conditions, the discharge value, computed from the river not gorged, has been used as the correct monthly mean inflow to Lake Erie.

65. The monthly mean discharge values of the Detroit River from January, 1860, to December, 1907, inclusive, are given in Table 20.

NIAGARA RIVER DISCHARGE.

66. The discharge of the Niagara River has been determined by measurements taken at the International Bridge, located at Buffalo, N. Y., and at a point about 1800 feet down stream at the "Open Section." These observations were begun in 1897 under the direction of E. E. Haskell, Engineer for

the United States Deep Waterways Commission. At the conclusion of this work, the United States Lake Survey continued the measurements in 1898, 1899, and 1900. These measurements have been reduced on the assumption that the outlet of Lake Erie is a submerged weir witth a broad, flat crest, whose upper nappe is about one mile in length and the lower one about two, with the crest section at or near the Buffalo Waterworks' Intake Pier. The Niagara River discharge formula, as derived, is:

$$D_{NIAGARA} = CbF^{\frac{1}{2}}\left(h_U + \frac{h_D}{2}\right). \qquad (31)$$

in which F = fall from Buffalo Breakwater Light-house, in Lake Erie, to Austin Street, in Niagara River,
h_U = upstream head on crest of submerged weir, determined by Buffalo Breakwater Light-house gage,
h_D = downstream head on crest of submerged weir, determined by Austin Street gage,

$C = -0.02458h_U + 2.550.$

556.35 = the average elevation of the crest of the weir above mean tide at New York,
b = width of crest section, at Waterworks' Intake, which is determined as follows: Compute the mean fall in the Niagara River from Buffalo Breakwater Light-house to Austin Street, according to the formula, $F = 0.02976X^2 - 0.4896X + 6.5828$, in which X = Lake Erie stage at Buffalo Breakwater Light-house gage above elevation 560 feet. Substitute this value for fall, or the actual fall between these two points in the equation, (Fall, Buffalo Breakwater Light-house to Waterworks' Intake = 0.4916 (Fall, Buffalo Breakwater Light-house to Austin Street) + 0.6553, and solve for fall from Buffalo Breakwater Light-house to Waterworks' Intake Section. Determine the corresponding stage of water at Waterworks' Intake Section by subtracting the fall from Buffalo Breakwater Light-house to Waterworks' Intake Section from Lake Erie stage as measured at Buffalo Breakwater Light-house. Then substitute in the equation, b = 80 (Waterworks' Intake stage above mean tide at New York) — 43598, and solve for the width of the crest section.

The monthly mean discharge values of the Niagara River, from January, 1860, to December, 1907, inclusive, are given in Table 21.

ST. LAWRENCE RIVER DISCHARGE.

67. The St. Lawrence River discharge formula has been determined from discharge measurements made by the United States Lake Survey in 1901 and 1902 at "Three Points Section," situated about 15 miles below Ogdensburg, N. Y., and 9 miles below the head of the Galop Rapids. During the measurements, no simultaneous gage readings were observed at Lock 27. Since the discharge equation is expressed in terms of Ogdensburg and Lock 27 gage heights, the latter have been computed for each measurement according to the equation, (Ogdensburg — 240) = 0.0006489 (Lock 27 — 240)^2 + 0.97085 (Lock 27 — 240) + 1.3502, which was derived from simultaneous monthly mean readings taken at the two places. This method was deemed most accurate, for, during the months when observations were taken, the slope between Ogdensburg and Lock 27 approximated very closely the mean slope computed by the above formula. It has been assumed that the submerged weir lies between Ogdensburg and Lock 27, near the head of the Galop Rapids, and the mean elevation of the crest of this weir is 230 feet above mean sea level at New York. The discharge equation, as deduced for summer flow, May to November, inclusive, before the Gut channel at the Galop Rapids was closed, is:

$$D_{\text{(summer) St. Lawrence}} = \frac{C_{oo} + C_{27}}{2} F^{\frac{1}{2}} \left(h_u + \frac{h_d}{2}\right). \quad (32)$$

in which C_{oo}, for the upstream head measured at Ogdensburg self-registering gage, is $= \frac{114430.485}{\frac{152.389}{h_u} + 1}$,

C_{27}, for the downstream head, measured at Lock 27, is $= \frac{54507.508}{\frac{59.445}{h_d} + 1}$,

F = fall, Ogdensburg to Lock 27,

h_u = upstream head on crest (elevation 230) of submerged weir, determined by Ogdensburg gage height,

h_d = downstream head on crest (elevation 230) of submerged weir, determined by Lock 27 gage height.

68. The slope in the river from Oswego and Ogdensburg to Lock 27, increases in the winter, due to the ice covering, which causes increased friction with the water and decreases the discharge for a given stage. The average increase in fall for the winter season, between Lock 27 and Ogdensburg, has

been determined as 0.31 foot. For any given stage at Lock 27, with mean summer slope to Ogdensburg, the discharge of the St. Lawrence River can be derived by formula (32). With this known river discharge and stage at Lock 27, and with Ogdensburg gage heights increased by 0.31 foot for average winter conditions, a solution for C in the submerged-weir formula has been made. This operation was repeated so as to cover the range in stage at these two gages.

69. The winter discharge equation, as deduced, covering the period from December to April, inclusive, and before the Gut channel at the Galop Rapids was closed, is:

$$D_i \text{ (WINTER) ST. LAWRENCE} = \frac{C_{oo.} + C_{27}}{2} F^{\frac{1}{2}} \left(h_U + \frac{h_D}{2}\right), \quad (33)$$

in which $C_{oo.}$, for the upstream head, measured at Ogdensburg self-registering gage in the winter season, is $= \frac{131202.913}{\frac{206.737}{h_U}+1}$,

C_{27}, for the downstream head, measured at Lock 27 in the winter season, is $= \frac{53597.993}{\frac{67.401}{h_D}+1}$,

F = fall, Ogdensburg to Lock 27,
h_U = upstream head on crest (elevation 230) of submerged weir, determined by Ogdensburg gage heights,
h_D = downstream head on crest (elevation 230) of submerged weir, determined by Lock 27 gage heights.

70. As previously stated, the winter months have been considered as December to April, inclusive. During many of these months, ice gorges have occurred in the river, above the Galop Rapids, which conditions have invalidated the winter-slope relation and caused abnormally high discharge values. Fortunately, below the Galop there are two more submerged weirs, one at the head of Rapide Plat, near Lock 24 on the Morrisburg Canal, and the other at the head of the Long Sault Rapids, near Lock 21 on the Cornwall Canal, at which points water-level observations have been made by the Canadian Government for many years.

71. Owing to lack of data, the Commission has been unable to derive a submerged-weir formula for the St. Lawrence River discharge based on the stage of water at the Rapide Plat and Long Sault Rapids, and has used the overfall-weir formula derived by the United States Lake Survey for these two locations, and has also used in a few instances the over-

fall-weir formula in terms of Lock 27, when ice gorges occurred at Lock 24 and Lock 21 and the slope in the river above the Galop was abnormal.

72. These discharge equations for the St. Lawrence River flow are:

$$D_{27\ \text{ST. LAWRENCE}} = 5732\ (2.80 + h_{27})^{\frac{1}{2}}, \tag{34}$$

$$D_{24\ \text{ST. LAWRENCE}} = 16.60\ (22.10 + h_{24})^{2.5}, \tag{35}$$

$$D_{21\ \text{ST. LAWRENCE}} = 316.0\ (8.30 + h_{21})^{2.3}, \tag{36}$$

where h_{27}, h_{24} and h_{21} are the gage readings above the old lock sill of each lock as zero.

73. In determining the monthly mean discharge of the St. Lawrence River for January, February, and March, from 1870 to 1907, inclusive, values have been deduced according to the submerged-weir and the three overfall-weir formulae. The minimum result in each case has been used as the most reliable value.

74. In 1903, the Canadian Government began work on closing the Gut channel, the smallest of the three channels at the head of the Galop Rapids. The damming of this outlet decreased the discharge of the St. Lawrence River for any given stage. According to the United States Lake Survey, this change in flow has been about 5½ per cent. less than that for the assumed original condition, January, 1860, to August, 1903, inclusive. This percentage change has been applied to the discharge equations for the period previous to September, 1903, and other discharge formulae deduced.

75. The formula as derived for summer conditions of flow of the St. Lawrence, after the Gut channel was closed, is:

$$D_{2\ (\text{SUMMER})\ \text{ST. LAWRENCE}} = \frac{C_{os.} + C_{27}}{2}\ F^{\frac{1}{2}}\left(h_v + \frac{h_o}{2}\right) \tag{37}$$

in which C for the upstream head, measured at Ogdensburg self-registering gage, is: $C_{os.} = \dfrac{104112.068}{\dfrac{146.326}{h_v} + 1}$,

C for the downstream head, measured at Lock 27, is:

$$_{27} = \frac{55685.721}{\dfrac{65.075}{h_p} + 1},$$

F = fall from Ogdensburg self-registering gage to Lock 27,
h_o = upstream head on crest (elevation 230) of submerged weir, determined by Ogdensburg gage heights,

h_D = downstream head on crest, determined by Lock 27 gage heights.

76. The St. Lawrence River winter discharge formula, after the Gut channel was closed, as deduced, is:

$$D_2 \text{ (WINTER) ST. LAWRENCE} = \frac{C_{og.} + C_{27}}{2} F l \left(h_v + \frac{h_D}{2}\right). \quad (38)$$

in which C for Ogdensburg self-registering gage is:

$$C_{og} = \frac{135093.09}{\frac{226.492}{h_v} + 1},$$

C for Lock 27 is: $C_{27} = \frac{52177.516}{\frac{69.799}{h_D} + 1}$.

The remaining factors are the same as for summer flow.

The monthly mean discharge values of the St. Lawrence River, from January, 1860, to December, 1907, inclusive, are given in Table 22.

DISCHARGE INCREMENTS OF THE RIVER OUTLETS OF THE GREAT LAKES SYSTEM.

77. The discharge increment, or rate of change of river flow per unit change in stage, varies in the several river outlets of the Great Lakes. It is not only different for each river but it also changes with the section and the stage. In general, the increment at mean stage increases with each river lower in this series. The Detroit River increment is greater than the St. Clair; likewise, the St. Lawrence River increment is greater than the Niagara. It also increases as each river is descended. On the Niagara River, the increment at Buffalo Light-house, Buffalo, for mean stage of Lake Erie, is 23400 cubic feet per second per foot, while at Grass Island, near the intake of the Niagara Falls Power Company, at Niagara Falls, N. Y., the increment is about 43000 cubic feet per second per foot. There are exceptions to this rule when the river section is contracted. At the head of the Whirlpool Rapids, in the Niagara River, a contracted section reduces the increment to about 9000 cubic feet per second per foot. In the St. Lawrence River, contracted sections occur at the head of the Rapide Plat and the head of the Long Sault Rapids. At the former, the increment is about 22500 cubic feet per second per foot, while at Lake Ontario it is 28100 cubic feet per second per foot. Table 23 gives the discharge increments, expressed in cubic feet per second per foot change in stage, of the several river outlets of the Great Lakes.

TABLE 23.

INCREMENTS OF DISCHARGE OF THE SEVERAL RIVER OUTLETS OF THE GREAT LAKES, EXPRESSED IN CUBIC FEET PER SECOND PER FOOT CHANGE IN STAGE.

River.	Location of Gage.	Stage.	Increment.
St. Marys.....	Sault Ste. Marie, Mich.,	601.91 (Mean)	18,500
		601—602	18,500
		602—603	18,500
St. Clair.....	Harbor Beach, Mich.,	581.44 (Mean)	18,900
		579—580	16,300
		580—581	17,500
		581—582	19,100
		582—583	20,900
Detroit.....	Windmill Point, Mich.,	575.40 (Mean)	20,600
		574—575	18,300
		575—576	20,900
		576—577	22,500
Niagara.....	Buffalo, N. Y.,	572.67 (Mean)	23,400
		570—571	19,600
		571—572	21,400
		572—573	23,200
		573—574	25,100
St. Lawrence....	Ogdensburg, N. Y.,	245.28 (Mean)	28,100
		244—245	26,800
		245—246	27,600
		246—247	29,300
		247—248	29,800

SUPPLY FACTORS OF GREAT LAKES.

78. The total supply (S) of water to a reservoir or lake depends on the inflow (I) or transmitted supply from another watershed, the precipitation (P) on the surface of the lake, the run-off (R) from the lake's watershed, and evaporation (E) from the lake's surface; or the outflow or discharge (D) from and storage (s) in the lake. Of these factors, for the Great Lakes, the transmitted supply (I), the discharge (D), and the storage (s), are known singly, while the value of precipitation (P), run-off (R), and evaporation (E), is known collectively.

79. The following equation expresses the total supply to any lake:

$$S = I + R + P - E = D \pm s. \qquad (39)$$

Now, $s = Ah$, where A is the area of the lake and h the depth in feet above any datum. Transposing and substituting in (39) the value of s, we have:

$$S - D = Ah \qquad (40)$$

80. The following equation shows the rate of change in the depth (dh) at any instant of time (dt):

$$(S - D)\,dt = A\,dh \tag{41}$$

Integrating with respect to t and h between the limits o and t and o and h, respectively, we have:

$$(S - D)\int_o^t dt = A\int_o^h dh \tag{42}$$

$$(S - D)\,t = Ah \tag{43}$$

81. An inspection of equation (43) shows that when S is greater than D the lake surface is rising and the storage is increasing, when S is less than D the lake surface is falling and the storage is decreasing; and when S is equal to D the lake surface remains at the same level and there is no change in the storage.

82. The local supply (L) to a reservoir or lake has been assumed as the water-yield from its own watershed. It is also, in a series of connecting watersheds, equal to the total supply (S) minus the transmitted supply or inflow (I) from the watersheds situated above.

83. The following equation expresses the local supply to any lake:

$$L = S - I = (D \pm s) - I = R + P - E \tag{44}$$

84. The known supply factors have been deduced for Lakes Superior, Michigan-Huron, Erie, and Ontario for the period of 48 years, from 1860 to 1907, inclusive. These results are shown in Tables 24, 25, 26, and 27, and Plates 2-17, inclusive.

85. For Lake Superior, the water levels at Marquette, Mich., have been assumed to represent the mean lake surface, and those at Sault Ste. Marie, Mich., (above the locks) have been used in computing the discharge of the lake's outlet. The stage readings on the first of the month for this lake and those lower in the series have been interpolated from the monthly mean readings. For Lake Michigan-Huron, the mean of the stage values for Milwaukee, Wis., and Harbor Beach, Mich., has been used for the mean lake surface. Lake St. Clair has been treated as a part of the Michigan-Huron watershed, and the Detroit River, as the natural lake outlet. Since 1900, water has been diverted from Lake Michigan through the Chicago Drainage Canal. The St. Clair River is the outlet to Lake Michigan-Huron, but, owing to the apparent changes in regimen prior to the first accurate discharge measurements in

1899, it became necessary to eliminate this river and use the Detroit, regardless of the fact that there have been many more discharge measurements of the St. Clair. The regimen of the Detroit River has, apparently, remained nearly constant during the period from 1860 to 1907, inclusive. For Lake Erie, the water levels at Cleveland, Ohio, have been used to represent the mean lake surface, and those at Buffalo, N. Y., to govern the outflow through the Niagara River. The volume of water diverted from the natural outlet of Lake Erie through the Erie and Welland canals has been estimated at 1000 and 1100 cubic feet per second, respectively. These amounts, added to the Niagara River discharge values represent the total outflow from Lake Erie. For Lake Ontario, the Oswego, N. Y., stage readings have been assumed to represent the mean water level of the lake. During periods in the spring, when the Oswego River was at flood stage, these water levels may be slightly in error. The outflow through the St. Lawrence River has been derived from the values of the Ogdensburg and Lock 27 gage heights, used collectively, except as heretofore noted.

86. Lake Superior Supply Factors. An inspection of Plates 2-5, inclusive, shows that Lake Superior had a maximum monthly mean stage of 604.08, in September, 1869, and a minimum of 600.76, in February, 1871. During the high water of 1876, Superior rose, in August, to 603.93. On several occasions, the lake level has fallen to about 601.0, or lower, as in 1879, 1880, 1892, and 1893. Since 1894, Superior has fluctuated between 601.46 and 603.54, a range of 2.08 feet, while the maximum fluctuation since 1860 has been 3.32 feet. The mean water level for the 48 years, 1860 to 1907, inclusive, was 602.32. The storage capacity of Superior is enormous, one foot depth on the lake surface being equivalent in volume to a constant inflow of 340100 cubic feet per second for one month. During the period which this investigation covers, the storage has been over + 200000 cubic feet per second, for a month, on several occasions. In May, 1876, May, 1888, and May, 1899, Superior stored + 207500, + 212600, and + 204100 cubic feet per second, respectively. In August, 1869, the lake stage increased 0.655 foot, equivalent to + 222800 cubic feet per second storage. The occurrence of the maximum storage in the month of August is most unusual. At other times, the lake surface has fallen almost as rapidly. In November, 1869, November, 1870, December, 1870, December, 1871, and December, 1897, the storage was — 168400, — 188800, — 173400, — 161600, and — 137700 cubic feet per second, respectively. The corresponding feet depths on lake surface are: — 0.495,

— 0.555, — 0.510, — 0.475, and — 0.405. For the three months of November and December, 1870, and January, 1871, Lake Superior fell from 602.47, on November 1st, to 601.06, on February 1st, a storage of — 1.41 feet. The outflow from Lake Superior through the St. Marys River has not shown the fluctuations so noticeable in the storage. In September, 1869, the river discharged 128700 cubic feet per second, and in September, 1876, 121800 cubic feet per second. These two values represent the maximum monthly mean discharge to date. On only two occasions has the monthly mean discharge fallen below 50000 cubic feet per second, and that occurred during February and March, 1893, when it reached 48200 and 48400 cubic feet per second, respectively. The total monthly mean supply or water-yield to Lake Superior has ranged between 333300 cubic feet per second, in August, 1869, and — 106600, in December, 1870, equivalent to 0.980 and — 0.313 foot depth on lake surface, respectively. A maximum monthly mean supply of + 200000 cubic feet per second, or more, has occurred in 21 of the 48 years. A minus monthly mean supply has occurred in 42 of the 48 years. Minus values have occurred in each month between October and April, inclusive, although December has been the prevailing one.

87. Lake Michigan-Huron Supply Factors. As shown on Plates 6-9, inclusive, the monthly mean stage of Lake Michigan-Huron has fluctuated between 583.58 and 583.60, in July, 1876, and June, 1886, respectively, and 579.00, in December, 1895, a range of 4.6 feet. Previous to 1886, the lake level had fallen to about 580.2, or 1.2 feet above the low water of 1895 and 1896, on only three occasions, March, 1869, March, 1872, and January and February, 1873. Since September, 1890, the monthly mean stage has not exceeded 581.5, except in July and August, 1905, and July, 1907, when it was 581.56, 581.54, and 581.56, respectively. The mean stage of Lake Michigan-Huron for the 48 years, 1860 to 1907, inclusive, was 581.38. As previously stated, in Table 1, the area of Lake Michigan-Huron is 45314 square miles. An increase in depth of one foot on this surface is equivalent to a constant inflow of 480700 cubic feet per second for one month. The storage on this lake, in May, 1873, and May, 1876, amounted to + 251400 and + 254800 cubic feet per second, respectively, with corresponding depths on surface of 0.523 and 0.530 foot. A monthly storage of + 150000 cubic feet per second is quite common. Occasionally, the high rate of storage extends over several months, as in April, May and June, 1876, when the average monthly increase for this period had a value of + 220300,

equivalent to a total change in stage of + 1.37 feet in three months. On the other hand, when the lake stage had fallen, as in August, September, October, November, and December, 1871, the average monthly decrease in storage had a value of — 183600 cubic feet per second, equivalent to a total decrease in stage of 1.91 feet in the five months. The minimum storage occurred in September, 1871, when it had a value of — 261500 cubic feet per second, equivalent to a depth on lake of — 0.544 foot. Values of — 150000 to — 200000 cubic feet per second have occurred frequently. The outflow through the Detroit River has ranged from about 275400, in July, 1883, to 105300, in February, 1874. The discharge of this river is dependent not only upon the stage of Lake St. Clair but also upon the fall to Lake Erie. The stage of Lake St. Clair is, in turn, dependent on the discharge from Michigan-Huron and on its outflow to Erie. A large discharge from Michigan-Huron raises Lake St. Clair quickly, while a high stage of Erie decreases the discharge of the Detroit River and raises Lake St. Clair by backwater. An increasing stage of Lake St. Clair with constant fall to Erie, or an increasing fall with the same St. Clair stage, gives increased discharge through the Detroit River.

88. Lakes Michigan-Huron and Erie do not rise and fall simultaneously. In some cases, the former will be rising and the latter falling. This is usually what occurs during the winter months of January, February, and March, and sometimes in December, April, and May. Ice gorges in the St. Clair or Detroit River hold back the water, thus depleting the supply to Erie and storing it in Michigan-Huron. When the gorge occurs in the St. Clair River, Lake St. Clair falls and the slope to Lake Erie becomes less than normal and that to Michigan-Huron greater. When the gorge occurs in the Detroit River, Lake St. Clair rises and the slope to Michigan-Huron is less than normal and that to Erie greater. If ice gorges of the same intensity should occur in the St. Clair and the Detroit rivers simultaneously, Lake St. Clair would probably not indicate the gorged condition, since the discharge increments of the two rivers would be decreased and the lake would remain at its normal level. By an inspection of the hydrograph of the Great Lakes, as shown on Plate 1, the effect of ice gorges in the St. Clair and Detroit rivers is seen. Attention is called particularly to the following months as indicating large gorges in the St. Clair River: February, 1865; March, 1877; January, 1884; February, 1886; April, 1901, and February, 1902. In each case, the stage of Lake St. Clair dropped and Michigan-

Huron rose. Large ice gorges in the Detroit River occurred in January, 1870, December, 1876, December, 1880, January, 1889, and February, 1895. This fact is substantiated by the extreme rise in Lake St. Clair and by the fall in Lake Erie. The total monthly mean supply to Lake Michigan-Huron has fluctuated between + 470800 cubic feet per second, in June, 1883, and — 32000 cubic feet per second, in September, 1871, equivalent to a depth on the lake of + 0.979 and — 0.067 foot, respectively. In May, 1873, and May and June, 1876, the total supply exceeded + 450000 cubic feet per second. In 10 of the 48 years, the monthly supply has been over + 400000 cubic feet per second. Monthly values of + 350000 cubic feet per second have occurred in over 60 per cent. of the years. Other months show a total supply of less than + 25000 cubic feet per second in many of these years. In April and May, 1873, May, 1876, and June, 1883, the local supply to Michigan-Huron was + 373000, + 365100, + 356400, and + 389100 cubic feet per second, respectively, corresponding to depth on lake of 0.776, 0.759, 0.741, and 0.809 foot, respectively. In September, 1871, the lake lost by evaporation 125700 cubic feet per second more than the actual precipitation on the lake surface and run-off of the tributary watershed. During the months from August to December, inclusive, a minus local supply has been common, in some cases extending over several months. From August to December, 1894, inclusive, evaporation on the lake surface exceeded the precipitation on the lake surface and run-off from the tributary watershed, and the stage of Lake Michigan-Huron dropped 1.3 feet.

89. Lake Erie Supply Factors. The monthly mean stage of Lake Erie (see Plates 10-13, inclusive,) during the period covered in this report, has risen to 574.52, in June, 1876. The minimum stage occurred in February, 1902, when Erie fell to 570.63. During the latter month, an extensive ice gorge occurred in the St. Clair River, which explains the extreme low stage of Erie at that time. Prior to that time, the minimum stage of Erie occurred in November, 1895, when it fell to 570.70. The monthly mean level has fluctuated through an extreme range of 3.89 feet, while the annual mean oscillation in lake level has been 2.53 feet. The mean stage of Erie, from 1860 to 1907, inclusive, was 572.60. The amount of storage, for a rise of one foot in the level of Lake Erie, is equivalent to a flow of 105700 cubic feet per second for one month. On but one occasion has the storage exceeded + 100000 cubic feet per second. In April, 1873, it had a value of + 103600, equivalent to a depth on lake surface of 0.98 foot. During the month

of January, 1865, the storage reached a minimum of —52900 cubic feet per second, corresponding to —0.50 foot on lake surface. A value nearly as small as the latter occurred in November, 1903, when the storage had a value of —49700, equivalent to —0.47 foot. The maximum monthly mean discharge from Lake Erie, 257800 cubic feet per second, equivalent to a depth of 2.44 feet on Lake Erie, occurred in June, 1876. The minimum, 168700 cubic feet per second, equivalent to a depth of 1.60 feet on lake surface, occurred in March, 1896. Ice gorges in the Niagara River, apparently, have had comparatively little effect on the outflow from Lake Erie. The maximum total supply of +314700 cubic feet per second to Erie, corresponding to a depth of +2.98 feet on lake, occurred in April, 1861. Large positive total supply values occurred in April, 1862, April, 1873, March and April, 1876, and June, 1883. The values for the several months are: +307,400, +309700, +295600, +289000, and +290300 cubic feet per second, respectively. In 16 out of the 48 years, a total monthly means supply of +275000 cubic feet per second has been exceeded. During the five-month period from February to June, 1876, inclusive, Erie had a monthly mean total supply greater than +250000 cubic feet per second, and the stage increased 1.82 feet. At other times, the total supply has decreased to less than half the maximum. The minimum, +146900 cubic feet per second, occurred in October, 1891, and November, 1903. The supply was nearly as low in January, 1865, and October, 1895, with values of +149300 and +148500 cubic feet per second, respectively. The local supply to Erie, apparently, has been very much less than to the lakes above. In April, 1873, January and February, 1874, and May, 1892, it exceeded +100000 cubic feet per second by 10600, 3200, 21600, and 9200, respectively. Minus values occur very frequently. In many years, the last six months give a minus local supply. From June, 1884, to March, 1885, inclusive, a minus local supply occurred during the entire period with an average monthly value of —40400. During this period, the lake fell from 574.14, in June, to 571.92, in March, a change in stage of —2.22 feet. The minimum monthly local supply to Erie of —63600 cubic feet per second, corresponding to a depth on lake surface of —0.60 foot, occurred in December, 1871. From August to November, 1867, inclusive, the monthly local supply was —57700, —60500, —61700, and —56500 cubic feet per second, respectively. Collectively, these values are equivalent to a depth on Lake Erie of 2.23 feet. During September, October and November, 1874, large successive local supply values of

— 50600, — 56100, and — 51200 cubic feet per second, respectively, occurred, equivalent to a total depth on Lake Erie of 1.49 feet. For September, October, and November, 1884, the monthly local supply was — 53100, — 57500, and — 50600 cubic feet per second, respectively. These values are, collectively, equivalent to 1.52 feet depth on Lake Erie.

90. Lake Ontario Supply Factors. Referring to Plates 14-17, inclusive, the maximum stage of Lake Ontario occurred in May, 1870, when the lake level had a value of 248.95. In 1861, 1862, 1863, 1864, 1867, 1876, 1883, 1884, 1886, 1887, and 1890, the stage exceeded 248.00. In November, 1895, the lake level dropped to 243.41, which has been the minimum stage during the 48 years from 1860 to 1907, inclusive. In two other years, the stage has fallen below 244.00. This condition occurred in January, November, and December, 1896, and January and February, 1897. This monthly fluctuation of Ontario is greater than that in any of the other Great Lakes. The maximum range in stage is 5.54 feet. Ontario fell from 248.48, in June, 1867, to 244.51, in January, 1868, a change in level of 3.97 feet. The mean stage of Lake Ontario, for the period from 1860 to 1907, inclusive, was 246.19. A foot depth on Lake Ontario is equivalent to a monthly flow of 76800 cubic feet per second. During March and April, 1873, and March, 1904, the monthly storage equalled or exceeded one foot depth on the lake surface, with corresponding storage values of + 79900, + 96000, and + 76800 cubic feet per second, respectively. Twelve of the 48 years had a monthly storage of + 50000 cubic feet per second, or more. During October and November, 1867, the minus storage exceeded — 50000 cubic feet per second, the values being — 53800, and — 57600 cubic feet per second, respectively. The discharge of the St. Lawrence River shows an extreme variation of about 130 per cent. This change in flow is small compared with rivers not having immense storage reservoirs at their sources. The maximum flow has been computed at 351200 and 350500 cubic feet per second, and occurred in May, 1862, and May, 1870, respectively. These values may be slightly too great on account of floods in the Oswego River causing abnormal gage readings for lake stage. These maximum discharge values have been approached in June and July, 1870, when there was little likelihood of the stage being affected by these local floods. In these two months, the flow has been computed at 344100 and 343200 cubic feet per second, respectively. The minimum flow has approximated 155000 cubic feet per second. In February, 1875, March, 1900, and, February, 1902, the discharge was

157900, 156600, and 152200 cubic feet per second, respectively. These extreme low discharges have been caused by ice gorges in the river. The minimum outflow, not caused by ice gorges, occurred in December, 1895, and December, 1896, when the discharge was 162500 and 164800 cubic feet per second, respectively. The total supply to Ontario has fluctuated between the maximum of + 382400 cubic feet per second, in April, 1870, and the minimum of + 154100 cubic feet per second, in February, 1875, a range of 228300 cubic feet per second. The equivalent depths on lake surface are 4.98 and 2.01 feet, respectively. In May, 1861, and April, 1862, the total supply was + 377400 and + 375600 cubic feet per second, respectively. Values of 325000 cubic feet per second have occurred in 17 of the 48 years. Since May, 1893, the total monthly supply has exceeded + 300000 cubic feet per second in but two years, 1903 and 1904. In 10 of the 48 years, the yield, or total supply, varied between + 155000 and + 175000 cubic feet per second during some months of the winter season. The Ontario local supply had a maximum of + 151800 cubic feet per second, in April, 1870. In January, 1881, the minimum value of — 34300 cubic feet per second occurred. In 7 years, the monthly mean local supply exceeded + 125000 cubic feet per second. In 17 of the 48 years, it exceeded + 100000 cubic feet per second. Minus values occurred frequently. The prevailing months for such values have been November, December, January, and February, although a minus local supply has occurred during all the months from August to February, inclusive.

MEAN MONTHLY SUPPLY FACTORS OF GREAT LAKES.

91. The mean monthly supply factors covering the period from 1860 to 1907, inclusive, have been derived from the monthly mean supply values of the several lakes for the 48-year period. Table 28 and Plate 18 give the results in numerical and graphical form. These curves show the mean monthly condition on Lakes Superior, Michigan-Huron, Erie, and Ontario. From Plate 18, Table 29 has been compiled, which shows the approximate date of maximum and minimum mean monthly values of stage, storage, outflow, total supply, and local supply of Lakes Superior, Michigan-Huron, Erie, and Ontario.

TABLE 29.

DATE OF MAXIMUM AND MINIMUM VALUES OF MEAN MONTHLY SUPPLY FACTORS OF THE GREAT LAKES.

LAKE.	Stage.	Storage.	Outflow.	Total Supply.	Local Supply.
Superior, maximum	Sep. 20	May 20	Sep. 1	May 25	May 25
Superior, minimum	Mar. 20	Dec. 10	Mar. 15	Dec. 15	Dec. 15
Michigan-Huron, maximum	Jul. 20	May 5	Aug. 1	May 10	May 5
Michigan-Huron, minimum	Feb. 1	Nov. 1	Feb. 20	Nov. 10	Oct. 25
Erie, maximum	Jun. 25	Apr. 5	Jul. 5	Apr. 20	Apr. 5
Erie, minimum	Feb. 10	Oct. 1	Feb. 20	Oct. 10	Oct. 1
Ontario, maximum	Jul. 1	Apr. 5	Jul. 1	May 5	Apr. 25
Ontario, minimum	Dec. 10	Sep. 5	Feb. 10	Jan. 20	Sep. 25

92. The mean monthly stage cycle on Lake Superior has fluctuated between 602.79, in September, and 601.77, in March, a change of 1.02 feet. A plus storage has occurred during the months of April to September, inclusive, while a minus storage has occurred during the months of October to March, inclusive. The maximum mean monthly storage has been 95900 cubic feet per second, while the minimum has been —91100. The discharge, or outflow, has increased from March 15th to September 1st, while it has decreased from September 1st to March 15th. The mean monthly outflow has ranged between 92800 and 68000 cubic feet per second. The total supply has increased values from December to May, and has decreased values from May to December. The mean monthly total supply has had a maximum value of 175700 cubic feet per second, and a minimum value of —10700 cubic feet per second. This minus value, which occurs in December, shows conclusively that the evaporation from Superior may be greater than the precipitation on lake surface and run-off from its watershed. The mean monthly supply, to Superior, in January, has been only 2300 cubic feet per second, which proves that evaporation on lake surface is nearly equal to the precipitation on lake surface and run-off from the tributary watershed for that month.

93. The mean monthly stage of Lake Michigan-Huron has fluctuated between 581.90, in July, and 580.93, in January and February, a range of 0.98 foot. The storage on Michigan-Huron has been positive from February to July, inclusive, while it has been negative from August to January, inclusive. The maximum and minimum mean monthly storage values have been +132300 and —112200 cubic feet per second, respectively. The mean monthly outflow through the Detroit River has fluctuated from 219700, in August, to 175600 cubic

feet per second, in February. This minimum discharge value is probably too large. The mean monthly total supply has had a maximum value of + 337700 cubic feet per second, in May, and a minimum value of + 96200, in November. The mean monthly local supply to Michigan-Huron has fluctuated between + 257800 cubic feet per second, in May, and + 8200 cubic feet per second, in October. During October and November, the local supply has been so small that the evaporation from the lake surface has been about equal to the precipitation on lake surface and run-off from the tributary watershed.

94. The mean monthly stage on Lake Erie has ranged from 573.24, in June, to 572.03, in February, a fluctuation of 1.21 feet. The storage on Erie has had a positive value from February to June, inclusive, and a negative value from July to January, inclusive. The mean monthly storage has had a maximum value of + 44100 cubic feet per second, in April, and a minimum value of — 31100 cubic feet per second, in September. The outflow has fluctuated between 225700 cubic feet per second, in July, and 198100 cubic feet per second, in February. The mean monthly total supply has had a maximum value of + 255700 cubic feet per second, in April, while it has fallen to a minimum value of +179200 cubic feet per second, in October. The mean monthly local supply on Erie has had a positive value from January to June, inclusive, and a negative value from July to December, inclusive. During these last six months, July to December, inclusive, the evaporation on the surface of Lake Erie has been greater than the precipitation on the lake surface and run-off from the tributary watershed. The maximum mean monthly local supply of + 56100 cubic feet per second occurred in April, while the minimum of — 31800 cubic feet per second occurred in October.

95. The mean monthly stage of Lake Ontario has ranged from 246.95, in June, to 245.57, in December, a fluctuation of 1.38 feet. The storage has shown a positive value from January to June, inclusive, and a negative value from July to December, inclusive. The mean monthly storage has had a maximum value of + 34800 cubic feet per second, in April, and a minimum value of — 28700 cubic feet per second, in September. The mean monthly outflow through the St. Lawrence River has fluctuated between 283600 cubic feet per second, in July, and 219300 cubic feet per second, in February. The mean monthly total supply has had a maximum value of + 297500 cubic feet per second, in May, and a minimum value of + 225500 cubic feet per second, in January. The mean monthly local supply to Ontario has ranged from + 83800

cubic feet per second, in April, to +18000 cubic feet per second, in September.

96. The maximum mean monthly stage of each lake of the Great Lakes has occurred at different times in the different lakes. This has been equally true with respect to the minimum stage. The maximum discharge of any lake does not occur at the time of the maximum total supply. The minimum discharge of any lake does not occur at the time of the minimum total supply. The maximum local supply of any lake does not occur at the same time as the maximum total supply; neither does the minimum local supply of any lake occur at the same time as the minimum total supply.

97. Table 30 shows the ratios, $R_{MAX.}$, between the maximum value of mean monthly discharge and the maximum value of mean monthly total supply for each lake in the system; the time interval in days, $T_{MAX.}$, which elapsed between the date of the occurrence of the maximum value of mean monthly total supply to any lake and that of the maximum value of mean monthly discharge from that lake; and the time interval, in days, $T_{MIN.}$, which elapsed between the date of the occurrence of the minimum value of mean monthly total supply to any lake and that of the minimum value of mean monthly discharge from that lake.

TABLE 30.

RATIOS—$R_{MAX.}$, $T_{MAX.}$, and $T_{MIN.}$

LAKE.	$R_{MAX.}$	$T_{MAX.}$	$T_{MIN.}$
Superior	0.524	98 days	91 days
Michigan-Huron	0.647	82 days	101 days
Erie	0.884	76 days	132 days
Ontario	0.955	56 days	20 days

98. The ratio, $R_{MAX.}$, increases with each succeeding lake in the Great Lakes system. The maximum mean monthly outflow from Superior has been about 52 per cent. of the maximum mean monthly total supply to that lake, while the maximum mean monthly outflow from Ontario has been about 96 per cent. of the maximum mean monthly total supply to that lake.

99. In order that a comparison of the several supply factors of the several lakes can be intelligently made, part of the data given in Table 28 has been expressed in cubic feet per second per square mile of watershed. Table 31 gives the mean

monthly values of storage, outflow, and total supply of Lakes Superior, Michigan-Huron, Erie, and Ontario in terms of the total watershed area, including lake surface, above the lake's outlet, and of local supply of the same lakes in terms of the tributary local watershed area including lake surface. An inspection of this table shows that the mean monthly outflow from these several lakes of the Great Lakes system has been remarkably uniform. The maximum value for Superior has been 1.22 cubic feet per second per square mile, while the minimum value has been 0.89 cubic foot per second per square mile. The maximum value for Michigan-Huron has been 1.00 cubic foot per second per square mile, while the minimum value has been 0.80 cubic foot per second per square mile. The maximum value for Erie has been 0.89 cubic foot per second per square mile, while the minimum value has been 0.78 cubic foot per second per square mile. The maximum value for Ontario has been 0.99 cubic feet per second per square mile, while the minimum value has been 0.76 cubic foot per second per square mile.

100. The mean monthly total supply to Superior has fluctuated between 2.31 cubic feet per second per square mile and —0.14 cubic foot per second per square mile. That to Michigan-Huron has fluctuated between 1.53 cubic feet per second per square mile and 0.44 cubic foot per second per square mile. That to Erie has fluctuated between 1.00 cubic foot per second per square mile and 0.70 cubic foot per second per square mile. That to Ontario has fluctuated between 1.03 cubic feet per second per square mile and 0.78 cubic foot per second per square mile.

101. The mean monthly local supply to Superior has fluctuated between 2.31 cubic feet per second per square mile and —0.14 cubic foot per second per square mile. That to Michigan-Huron has fluctuated between 1.79 cubic feet per second per square mile and 0.06 cubic foot per second per square mile. That to Erie has fluctuated between +1.62 cubic feet per second per square mile and —0.92 cubic foot per second per square mile. That to Ontario has fluctuated between +1.62 cubic feet per second per square mile and 0.55 cubic foot per second per square mile. The average local supply to Erie is considerably less than that to the other lakes. This is explained in part by the southerly position of the lake in the chain, the general direction of its principal axis coinciding with the direction of the prevailing winds, its shallow depth, and errors in winter discharge values of Detroit River,—all of which tend to decrease the local supply factor.

102. A comparison of the total supply values with the outflow or discharge values, expressed in cubic feet per second per square mile, shows the regulating effect of reservoirs on stream flow. Without reservoirs, the run-off from the lake's watershed is discharged immediately, while, with reservoirs, the run-off is stored and discharged at an approximate uniform rate.

THE REGULATION OF LAKE ERIE AS PROPOSED BY THE UNITED STATES BOARD OF ENGINEERS ON DEEP WATERWAYS.

103. The United States Board of Engineers on Deep Waterways, in 1900, reported on the regulation of Lake Erie, in appendix 6 of their report. The scheme, as proposed by them, consisted of a submerged weir, with regulating sluices, at the outlet of Lake Erie near the angle in the Bird Island Pier, by which the level of the lake might be held at or near some fixed stage. The report says:

"The regulation of the level of the lake implies the maintenance of its surface at or near some fixed stage, to accomplish which the discharge must be so controlled that it will be at all times approximately equal to the difference between the supply of water to the lake and evaporation from the lake surface."

And further, in relation particularly to Lake Erie, the report states:

"To regulate the level of Lake Erie so as to maintain its surface near some fixed place of reference will require such control of the outflow through Niagara River that the storage which would naturally occur in the lake will be discharged during the first half of the year and the outflow will be diminished a like amount during the last half of the year. This modification of outflow will not materially change the total volume of discharge for any entire year and will amount to only one-fifth of the variation of discharge of the river for different years under present conditions. The effect of this modification of flow through Niagara River, on the level of Lake Ontario, will be to slightly increase the rate of rise in the spring and make the date of maximum stage a little earlier."

104. The scheme of regulation, as proposed by the Board of Engineers on Deep Waterways, is to not allow the monthly mean stage of Lake Erie, at Buffalo, to rise above 574.5 feet, old levels, or 574.7 feet, 1903 levels, above mean tide at New York. The minimum monthly stage of lake surface, under regulation, is not definitely stated, but it is intimated to be about 573.7 feet, 1903 levels, in the following paragraphs taken from their report:

(1) "The three months in which the supply was materially in excess of the discharge for proposed regulated stage were February, March, and April, during which the excess averaged 19000 cubic feet per second, corresponding to a rise of 0.2 foot in February, 0.2 foot in March, and 0.15 foot in April. Hence, if the level of the lake, when regulated, should be allowed to fall 0.6 foot every year after the close of navigation, it is probable that the excess of supply over discharge would never cause the surface to rise above the plane of regulation."

(2) "In the fall of 1875, the discharge of Niagara River was 60000 cubic feet per second less than the capacity of the regulating works; and, if the lake had been regulated, with the sluices of the regulating works all open, the surface would have been lowered one foot in about two months, or sufficient to have stored the excessive supply which occurred in the spring of 1876, with a margin of 0.4 foot for contingencies."

105. According to the discharge equation determined by the Board of Engineers on Deep Waterways, the maximum discharge of Niagara River was 277270 cubic feet per second, with the lake regulated at stage 574.70, 1903 levels, and the minimum discharge was 178000 cubic feet per second at stage 570.70, 1903 levels. The discharge formula of Niagara River, deduced by the International Waterways Commission, is based upon more complete data and gives the maximum discharge as 261500 cubic feet per second at 574.7, 1903 levels, and the minimum as 166700 cubic feet per second at stage 570.7, 1903 levels. In this report, the latter discharge values are used instead of those of the Board of Engineers on Deep Waterways.

PRACTICAL REGULATION OF LAKE ERIE BETWEEN STAGES 573.7 AND 574.7, 1903 LEVELS.

106. In working out a practical scheme for regulation, it is quite necessary to set a definite elevation for the regulated stage of Lake Erie at the beginning of each month. The stage values used in this investigation are given in Table 32.

TABLE 32.

STAGE OF LAKE ERIE DESIRED ON FIRST OF MONTH, WITH REGULATED CONDITIONS.

MONTH.	Stage Desired at Beginning of each Month.	MONTH.	Stage Desired at Beginning of each Month.
January 1,	573.8	August 1,	574.0
February 1,	573.7	September 1,	574.0
March 1,	573.7	October 1,	574.0
April 1,	573.8	November 1,	574.0
May 1,	573.9	December 1,	573.9
June 1,	574.0	January 1,	573.8
July 1,	574.0		

107. The maximum desired stage of water from June 1st to November 1st, inclusive, as shown in the above table, allows 0.7 foot for contingencies, which, as will be seen, is not adequate. The regulation of the elevation of the level of Lake Erie between stages 573.7 and 574.7 is a difficult proposition on account of the variation in total supply. It is impossible

to estimate this factor with any degree of accuracy on account of the fluctuation of inflow, precipitation, run-off, and evaporation. This fact is very strongly brought out in the data and results shown in Table 33 and Plate 19, "Regulation of Lake Erie between stages 573.7 and 574.7." The difference between the expected total supply and the actual total supply for any one month has been as great as +47800 cubic feet per second, in April, 1891, and —40200 cubic feet per second, in April, 1892, which would have caused a difference in the expected change in stage of Lake Erie of 0.4 to 0.5 foot. In June, 1892, (see Table 33) the lake level is supposed to have reached 574.0 on the 1st of July, and regulating works are assumed to have been set to give a discharge that would bring the lake to this stage by the first of the following month, but, owing to the increase in the actual total supply over the expected total supply, the lake would have risen to 574.64, which is 0.64 foot more than the desired and estimated stage. This unlooked-for variation in a high-water year, such as 1876, might prove disastrous if the lake level were at or near stage 574.7. By examining Table 33, it is also seen that the regulated level of Lake Erie would have fallen, in most years, during some of the winter months, to 573.3, approximately, or 0.4 foot below the minimum stage set by the Board of Engineers on Deep Waterways, but would have risen above 573.7 by the opening of the season of navigation. With the proposed scheme of regulation, for the period from 1890 to 1906, inclusive, the level of Lake Erie would have risen 0.04 foot above 574.7, in June, 1892.

108. The period from 1890 to 1906, inclusive, does not include an extreme high-water year. If the proposed scheme of regulation had occurred in 1876, when the monthly mean stage of Lake Erie reached 574.5, in June, then the assumed maximum level (574.7) would have been exceeded, during April to July, inclusive, by 0.03, 0.19, 0.20, and 0.05 foot, respectively, (see Table 33).

109. During the period from 1890 to 1906, inclusive, with regulation, the mean level of Lake Erie would have been raised from 572.1 to about 573.9, an increase in mean stage of 1.8 feet. During the low-water year of 1895, the mean annual level, with regulation, would have been 2.57 feet higher than the actual stage. The extreme low monthly mean stage of 570.71, in November, 1895, would have been raised by regulation to 573.59, an increase of 2.88 feet. The actual oscillation in monthly mean water level of Lake Erie has been about 3.89 feet. With regulation as proposed, the range of monthly

mean oscillation would have been reduced to 1.43 feet during the year, and to 1.14 feet during the navigation season.

110. Perfect regulation is impossible. The monthly increase in stage of Lake Erie, with natural conditions, is frequently 0.4 to 0.5 foot; occassionally exceeds 0.8 foot; and has been as great as 0.98 foot. Daily oscillations in the stage are occasionally as large as 7 or 8 feet, and hourly variations sometimes exceed 2 feet. Southwesterly storms on the lake raise the water level at Buffalo and lower it at Amherstburg by several feet from the normal. This difference of level has been as large as 15 feet with the severest storms. To control this daily and hourly variation in stage of Lake Erie within small limits is impossible.

EFFECT OF REGULATION OF LAKE ERIE, BETWEEN STAGES 573.7 AND 574.7, ON WATER LEVELS OF LAKE ONTARIO AND ST. LAWRENCE CANALS.

111. The effect of the regulation of the stage of Lake Erie, between 573.7 and 574.7, on the water levels of Lake Ontario, for the period from 1890 to 1906, inclusive, is shown on Plate 20, which illustrates the increased range in stage of Lake Ontario and the detrimental effect to navigation in the St. Lawrence canals due to the proposed regulation of Lake Erie under the scheme proposed by the Board of Engineers on Deep Waterways.

PRACTICAL REGULATION OF LAKE ERIE BETWEEN STAGES 572.0 AND 574.5, 1903 LEVELS.

112. Inasmuch as it is deemed impracticable to regulate the monthly mean stage of Lake Erie between stages 573.7 and 574.7 feet above mean tide at New York, as proposed in the plan of the Board of Engineers on Deep Waterways, the investigation was continued to determine the limits between which the regulation of the monthly mean stage of Lake Erie would be practicable.

113. As in the previous plan of lake regulation, a definite elevation for the stage of the lake on the first of each month has been assumed. These values represent the limits within which it would be necessary to attempt to hold the stage of Lake Erie so that the maximum and minimum monthly mean water levels of 574.5 and 572.0, respectively, would not be exceeded. Table 34 shows the assumed elevations desired on the first of month, of the water surface of Lake Erie, for regulation of its monthly mean stage between 572.0 and 574.5.

TABLE 34.

STAGE OF LAKE ERIE DESIRED ON FIRST OF MONTH WITH LAKE REGULATED BETWEEN 572.0 AND 574.5.

MONTH.	Stage Desired at Beginning of each Month.	MONTH.	Stage Desired at Beginning of each Month.
January 1,	572.3	August 1,	572.5
February 1,	572.2	September 1,	572.5
March 1,	572.2	October 1,	572.5
April 1,	572.2	November 1,	572.5
May 1,	572.3	December 1,	572.4
June 1,	572.4	January 1,	572.3
July 1,	572.5		

114. An inspection of Table 34 shows that 2.0 feet and 0.2 foot have been allowed for the actual fluctuations from the desired maximum and minimum monthly mean stages, respectively, of Lake Erie, with regulation. This extreme allowable fluctuation from the desired maximum is necessitated by the extreme high water of 1876, during which year the surface of Lake Erie, at Buffalo, reached a mean level of 574.49, in June, or but 0.01 foot less than the maximum monthly mean stage allowable with regulation.

115. As 1876 is the controlling high-water year, so 1895 is the controlling low-water year. Computations have been made for these two extreme years instead of for the period from 1890 to 1906, inclusive, as in the investigation of the scheme outlined by the Board of Engineers on Deep Waterways.

116. Table 35 and Plate 21 show that, with regulation, the water levels of Lake Erie, at Buffalo, differ but slightly from the actual levels for the year 1876, while for the low-water year of 1895 the annual mean level would be increased from 571.26 to 572.33, a change of + 1.07 feet, and the mean level for the extreme low-water months of November and December (both in the navigation season) would be increased from 570.71 and 570.97 to 572.09 and 572.34, respectively, or a change of + 1.38 feet and + 1.37 feet, respectively.

EFFECT OF REGULATION OF LAKE ERIE, BETWEEN STAGES 572.0 AND 574.5, ON WATER LEVELS OF LAKE ONTARIO AND ST. LAWRENCE CANALS.

117. Any change in the outflow of Lake Erie will change the water levels of Lake Ontario. If the inflow to Ontario is increased, the lake level will rise, and with decreased inflow the

level will fall. Table 36 and Plate 21 show the effect on the water levels of Lake Ontario for the years of 1876 and 1895, if Lake Erie stage had been regulated between stages 572.0 and 574.5 for those years. The effect of the regulation of Lake Erie would have been to increase the fluctuation in stage of Lake Ontario, causing higher stage in spring and lower stage in the autumn than under actual conditions.

118. For the high-water year of 1876, during which time the regulated inflow would have differed but slightly from the actual, there would have been no appreciable increase in the fluctuation in stage on Lake Ontario, and at no time during the year would the regulated stage differ from the actual by more than 0.12 foot. In 1895, however, a low-water year on Lake Ontario as well as on Lake Erie, the fluctuation would have increased with the result that during the months from September to December, inclusive, the regulated stages would have fallen to 243.70, 243.26, 243.08, and 243.33, respectively, or 0.34, 0.38, 0.33, and 0.18 foot, respectively, below the actual stages for those months.

119. During an extended period, such as from 1890 to 1906, inclusive, differences of 0.4 to 0.5 foot between the actual stage of Lake Ontario and the stage that would have prevailed under regulated conditions on Lake Erie would be of frequent occurrence. Unfortunately, these variations, with respect to actual stage, are generally negative during the period of low water and positive during the period of high water. Such conditions, caused by regulating Lake Erie, would injuriously affect navigation in the St. Lawrence canals and would decrease the draft of vessels by 0.4 to 0.5 foot, in the Galop canals, and 0.7 to 0.8 foot, in the Morrisburg canals. Barges and tows that now load to 14 feet draft would be compelled to load to not more than 13.2 or 13.3 feet draft during September, October, and November, in most years, and in some years, during the entire season of navigation.

EFFECT OF REGULATION OF LAKE ERIE, BETWEEN STAGES 572.0 AND 574.5, ON WATER LEVELS OF NIAGARA RIVER.

120. By the proposed system of regulation, the stage of water in the Niagara River would not fluctuate through any greater range than under actual conditions. During the winter months, more frequent low water would probably occur under regulation than under actual conditions, in which case the power companies at Niagara Falls would probably have more difficulty in keeping the channels to their intakes free

from ice. During the fall months, navigation in the river might be slightly interfered with owing to the storage in the lake of a part of the natural discharge.

EFFECT OF REGULATION OF LAKE ERIE, BETWEEN STAGES 572.0 AND 574.5, ON WATER LEVELS OF LAKE ST. CLAIR, LAKE MICHIGAN-HURON AND CONNECTING WATERS.

121. By the proposed regulation of Lake Erie between stages 572.0 and 574.5, the mean level of this lake would have been raised about 1 foot. This increase in stage would have decreased the mean slope in the Detroit River and would have caused Lake St. Clair to rise until the discharge through the Detroit River had a value equal to the discharge under natural conditions for the same period. An examination of Tables 8 and 9 shows that the mean stage of Lake St. Clair, at Windmill Point, was 575.40, and that of the lower end of the Detroit River, at Amherstburg, was 572.84. From equation 30, the discharge of the Detroit River is computed to be 204900 cubic feet per second for mean stages of 575.40, at Windmill Point, and 572.84, at Amherstburg. For this river-discharge value and with the stage at Amherstburg increased by 1.0 foot, the amount that mean level of Lake Erie would have been raised by regulation, it is found that the stage of Lake St. Clair, at Windmill Point, would eventually rise 0.61 foot. This value represents the effect on the stage of Lake St. Clair due to the increase of 1.0 foot in mean stage of Lake Erie under regulation.

122. The rise between actual and regulated low-water stage of Lake Erie would be greater than the corresponding rise between actual and regulated high-water stage. The effect of this would be to slightly lessen the discharge of the Detroit River at low stage and to slightly increase it at high stage.

123. As backwater from Lake Erie raises the water level of Lake St. Clair, so backwater from Lake St. Clair raises the water level of Lake Michigan-Huron. For a given flow in the Detroit River, an increase in the stage of Lake Erie causes an increase in the stage of Lake St. Clair; likewise, for a given flow in the St. Clair River, an increase in the stage of Lake St. Clair causes an increase in the stage of Lake Michigan-Huron. By the method used above, the effect on the water level of Lake Michigan-Huron, caused by 0.61 foot backwater on Lake St. Clair, due to the regulation of Lake Erie, has been computed to be 0.27 foot rise.

124. A study of Plate 21 shows that for a year of excessive, or above-normal supply, such as 1876, the regulation of Lake Erie would not materially improve navigation. In 1895, a year of deficient supply, the mean level during the eight-month season of navigation would have been increased from 571.31 feet, under natural conditions, to 572.41, under regulated conditions, and navigation on Erie would have been improved by an increased stage of 1.1 feet. The regulation of Lake Erie, between stages 572.0 and 574.5, would raise extreme low stage for the navigation season by at least 1 foot, without an appreciable increase in the extreme high stage. This increase in low stage is equivalent to deepening every harbor and channel in Lake Erie by that amount; in the Detroit River and Lake St. Clair, by at least 0.61 foot; and in the St. Clair River and Lake Michigan-Huron by at least 0.27 foot.

REGULATION OF LAKE SUPERIOR.

125. The regulation of the stage of Lake Superior has been suggested as a means (first) for improving navigation on that lake, and (second) to compensate for the diversion of water from Lake Michigan-Huron through the Chicago Drainage Canal.

126. This Commission has already recommended in its report upon the conditions existing at Sault Ste. Marie that "the level of St. Marys River, above the rapids, shall be maintained between the elevations 601.7 and 603.2 above mean tide at New York." The monthly mean stage of St. Marys River, above the rapids, has not risen above 603.2 since 1860, except in September and October, 1869, and July, August, and September, 1876. It has fallen below 601.7 on numerous occasions, generally during the winter months. In 1879 and 1891, the monthly mean stage did not exceed 601.5, while in 1892 it exceeded 601.7 in only one month. The fall in the water level of the St. Marys River above the rapids, below 601.7, for the ice months of January to April, inclusive, does not interfere with navigation on Lake Superior. The monthly mean water level of Lake Superior was below 601.7 about 20 per cent. of the navigation season (May to December, inclusive), from 1860 to 1888, inclusive. For this cycle of years, the regimen of the St. Marys River had not been materially altered by artificial works. With the completion of the International Bridge piers and approaches in 1888, and the shutting off of spans 1 and 2 of this bridge from the rapids by the Chandler-Dunbar Water Power Company, in 1892, these two principal obstructions to the natural outflow from Lake Superior have

raised the water level so that it has not fallen below 601.7 more than about 2 per cent. of the navigation season from 1893 to 1907, inclusive. The difference cannot be attributed to the variation in the total supply, or water-yield, to Lake Superior; for, as a matter of fact, the average total supply for the period from 1860 to 1888, inclusive, was about 4400 cubic feet per second greater than for the period from 1893 to 1907, inclusive.

127. The construction of the compensating works at the head of the St. Mary's Rapids by the Michigan Lake Superior Power Company, in 1901 and 1902, cut off a flow of about 9900 cubic feet per second. The 8500 cubic feet per second of water used by this company since 1905 nearly neutralizes the effect of these works.

128. The regulation of Lake Superior during the navigation season, between the elevations 601.7 and 603.2, as measured by the level of the St. Marys River above the rapids, has been accomplished under the conditions that did exist, and no further works seem to be necessary until a change in the artificial diversions at Sault Ste. Marie is made.

129. If the monthly mean level of Lake Superior were to be controlled during the navigation season within a smaller fluctuation than 1.5 feet, then the outflow through the St. Marys River would have to be artificially controlled. In order to eliminate the monthly mean fluctuation in large natural reservoirs, such as Lake Superior and the other lakes in this system, it would be necessary to increase the fluctuations of outflow to correspond to the fluctuations of total supply to that reservoir. To accomplish this result on Lake Superior, the monthly mean outflow would have had a maximum value of 333300 cubic feet per second, in August, 1869, and a minimum value of —106600 cubic feet per second, in December, 1870. Such fluctuations in outflow are impossible, since the minimum discharge of any stream is zero. When the total supply is minus, the level of the lake or reservoir will fall even if the outflow is entirely shut off.

130. The question that now presents itself, since perfect regulation of Superior is impossible, is: Can the fluctuations in stage of Lake Superior be materially reduced; and if so, what would be the effect on the lower lakes. An examination of Table 24 shows that during November and December, 1870, and January, 1871, the total monthly supply to Lake Superior for these three consecutive months was —99500, —106600, and —42900 cubic feet per second, respectively, equivalent, collectively, to a total depth on the lake surface of —0.732 foot.

The level of Lake Superior actually fell 1.41 feet during this period, but, even if the outflow through the St. Marys River had been entirely shut off, the lake would still have fallen over eight and three-quarters inches. During May, June, and July, in the high-water year of 1876, the total monthly supply to Lake Superior was 303300, 291200, and 205000 cubic feet per second, respectively,—a total of 799500 cubic feet per second, equivalent to a depth on lake surface of +2.351 feet. The outflow through the St. Marys River for the corresponding period was 95800, 109200, and 120000 cubic feet per second, respectively, or an average monthly flow of 108300 cubic feet per second. Granting that this enormous supply of water could have been predicted,—an impossibility—and that the St. Marys River could have discharged twice the average monthly outflow, or 216600 cubic feet per second, for three months, through artificial works and channels, which would be very costly to construct, Lake Superior would still have risen over 5¼ inches.

131. If the monthly oscillations in stage of Lake Superior could be materially reduced, then the monthly mean flow through the St. Marys River would fluctuate more than it actually does. Under present conditions, the outflow through the St. Marys River is the greatest during August, September, and October, when the stage of Lake Michigan-Huron is falling very rapidly. Under these natural conditions, the water from Lake Superior aids in the attempt of nature to hold the stage of Lake Michigan-Huron at a fixed elevation. If the outflow from Lake Superior in an average year were increased as much as 50 per cent. during August, September, and October, the level of Lake Michigan-Huron would be raised only about 0.1 foot per month for these months, since the discharge through the St. Marys River is not the supply factor that produces the principal effect on the stage of Lake Michigan-Huron.

132. These cases show, first that the artificial regulation of Lake Superior would not materially decrease the present fluctuation of water level; second, that Lake Superior is one of the best naturally regulated bodies of water in the world; and third, that the effect of the artificial regulation of the level of Lake Superior on the level of Lake Michigan-Huron would produce only insignificant results.

DIVERSION OF WATER THROUGH CHICAGO DRAINAGE CANAL, THE EFFECT OF DIVERSION ON LAKES MICHIGAN-HURON, ERIE, AND ONTARIO, AND THE REGULATION OF LAKE SUPERIOR TO COMPENSATE FOR DIVERSION AT CHICAGO.

133. The Chicago Drainage Canal has diverted water from Lake Michigan-Huron since 1900. This has lowered the level of Lakes Michigan-Huron, St. Clair, Erie, and Ontario, regardless of the fact that these lakes are at higher stages than they were when the canal was opened. These higher stages are due to the increase in the quantity of water supplied since 1900. If this supply had not been increased, then the stages of the lakes would have been actually less. Plates 22, 23, and 24 show the monthly loss of level on Lakes Michigan-Huron, Erie, and Ontario, respectively, under the actual diversion through the Chicago Drainage Canal, and also under assumed diversions of 10000 and 14000 cubic feet per second.

TABLE 37.

LOSS OF LEVEL ON LAKES MICHIGAN-HURON, ERIE, AND ONTARIO UNDER THE ACTUAL DIVERSION AND UNDER ASSUMED DIVERSIONS OF 10000 AND 14000 C. F. S. THROUGH THE CHICAGO DRAINAGE CANAL, 1900-1907, INCLUSIVE.

LAKE.	LOSS OF LEVEL IN INCHES.		
	Actual Diversion.	Assumed Diversion of	
		10000 c. f. s.	14000 c. f. s.
Michigan-Huron	2-5/8	6-1/2	9-3/8
Erie	2-1/2	5-7/8	8
Ontario	1-7/8	4-1/4	6

134. The stage of Lake Michigan-Huron is 2⅝ inches lower than it would have been if there had not been any water diverted through the Chicago Drainage Canal. Likewise, the stages of Lake Erie and Lake Ontario are 2½ and 1⅞ inches lower, respectively, than they would have been with no diversion at Chicago. If the quantity of water diverted through the canal had been as much as 10000 or 14000 cubic feet per second, then the effect would have been proportionately greater.

135. Since the effect of the diversion is to lower the level of the lakes and connecting channels of the Great Lakes system, with the exception of Lake Superior and the upper St. Marys River, and as this effect will increase with the increase in the quantity of water diverted, therefore, the ques-

tion presents itself: Can the present diversion or future diversions through the Chicago Drainage Canal be compensated for by the use of Lake Superior as a storage reservoir, so that the level of the lakes below Superior will not be lowered?

136. The longest low-stage period of outflow from Lake Superior has been selected in order to obtain a solution to the question. An examination of Plates 2 to 5, inclusive, shows that such a period occurred between June, 1888, and August, 1893. The average flow for the low-water year of 1892 was 65700 cubic feet per second. Assuming a continuous discharge from Superior of the average flow for that year, and, in addition, first, 4000 and, second, 14000 cubic feet per second, respectively, to compensate for a diversion of these amounts through the Chicago Drainage Canal, or a total continuous discharge of, first, 69700 cubic feet per second, and, second, 79700 cubic feet per second, respectively, between June 1, 1888, and August 31, 1893, then the regulated stages of all the lakes in the Great Lakes system would have differed materially from the actual stages. Plate 25 and Tables 38, 39, 40, 41, and 42 show these changes in stage of Lakes Superior, Michigan-Huron, Erie, and Ontario, due to regulation of outflow from Lake Superior to compensate for diversions through the Chicago Drainage Canal of 4000 and 14000 cubic feet per second.

137. To compensate for a diversion of 4000 cubic feet per second through the Chicago Drainage Canal, with the continuous discharge of water from Lake Superior of 69700 cubic feet per second between June 1, 1888, and August 31, 1893, the stage of the St. Marys River, as measured at Sault Ste. Marie, (above the locks) would have been higher than it was actually. In August, 1893, the level of Superior would have returned to approximately the actual stage. Under assumed conditions, the mean stage of Lake Superior would have been increased during the period from June, 1888, to August, 1893, at the expense of the decrease in stage of Lakes Michigan-Huron, Erie, and Ontario. The cumulative effect of the constant discharge of 69700 cubic feet per second from Lake Superior during this five-year period would have been to lower the monthly mean stage of Lake Michigan-Huron from 579.88 to 579.53, and from 579.82 to 579.48, in November and December, 1891, respectively. These stages would have been only 0.36 and 0.48 foot higher, respectively, than the actual stages for the corresponding months of November and December in the extreme low-water year of 1895, and would have

been 0.23 and 0.28 foot lower, respectively, than the mean stage for the entire navigation season of 1895, when the shipping interests were so seriously affected. This constant discharge of water from Lake Superior would also have lowered the monthly mean stage of Lake Erie from 571.21 to 570.89, and from 571.28 to 570.96, in November and December, 1891, respectively, which would have been only 0.19 and 0.19 foot higher, respectively, than the actual stages in November and December, 1895. The monthly mean stage of Lake Ontario would have been decreased by this discharge from Lake Superior from 244.44 to 244.19, and from 244.41 to 244.16, in November and December, 1891, respectively.

138. At the end of August, 1893, the water stored in Lake Superior would have been delivered to the lower lakes, and no storage water would have been available, in addition to the actual supply, to compensate for the diversion of water through the Chicago Drainage Canal, and prevent the mean levels of Lakes Michigan-Huron, Erie, and Ontario falling below the actual stages.

139. The monthly mean discharge of the St. Marys River was greater than 69700 cubic feet per second in September, October, and November, 1893. This excess would have allowed 6900, 5800, and 4800 cubic feet per second of water, respectively, to have been stored in Lake Superior in these months. The storage of this volume of water would have temporarily taken it away from the supply to Lake Michigan-Huron, and would have lowered the level of that lake temporarily. Later, when this stored water would have been discharged into the lakes below, their stages would have been the same as under natural conditions, and during the interval between the storage and discharge of this water the diversion of water through the Chicago Drainage Canal would have lowered the mean level of Lakes Michigan-Huron, Erie, and Ontario as it has under actual conditions. If the outlet were to have been artificially changed so that the St. Marys River could have discharged 4000 cubic feet per second in addition to the actual discharge, beginning with September, 1893, in order to compensate for an assumed diversion of this amount at Chicago, then it would have been only a few years before Lake Superior would have fallen so low in stage that navigation would have been seriously interfered with.

140. To compensate for a diversion of 14000 cubic feet per second through the Chicago Drainage Canal, with the continuous discharge of water from Lake Superior of 79700 cubic feet per second between June 1, 1888, and August 31, 1893,

the stage of the St. Marys River, as measured at Sault Ste. Marie, (above the locks) would have been lower by 1.4 feet than it was actually. This increased discharge from Lake Superior would produce the same effect on the lower lakes as the effect of the previous discharge of 69700 cubic feet per second, since the increased outflow from Lake Superior would be taken by the additional diversion through the Chicago Drainage Canal. The stage of the St. Marys River, at Sault Ste. Marie, (above the locks) would have fallen, in May, 1893, to slightly below 600.0, which would have seriously interfered with the navigation of Lake Superior by the present lake vessels. At the end of this five-year period, the level of Lake Superior would have been extremely low and water would not have been available for storage in Lake Superior for the next low-water period.

141. The annual mean stage of the St. Marys River, above the locks, fell to 600.96, in 1879. This minimum value must not be taken as a criterion for permissible low water for navigation purposes; neither should it be assumed that the minimum annual mean stage on the remaining lakes, as a permanent level, would be satisfactory to navigation.

142. The artificial storage of water in Lake Superior must be commenced by shutting off the transmitted supply to the lakes below Superior in the Great Lakes system. When the stored water is allowed to flow from Lake Superior, the total supply to Lakes Michigan-Huron, Erie, and Ontario will be the same as under actual conditions, and the mean level of these lakes will remain unchanged.

143. An artificial storage of water in Lake Superior has taken place, beginning with the construction of the International Bridge and its approaches in 1888. The storing of this water in Superior has withheld it temporarily from the lakes below, and, as a result, the stages of the latter have been changed from what they would have been if there had been no artificial changes in the outlet to Lake Superior. Plates 26, 27, 28, and 29 show the monthly mean stages of the Great Lakes under actual conditions and as they would have been if no artificial works had been built in the upper St. Marys River.

144. An inspection of Plate 26 shows that the artificial storage of water in Lake Superior, created by the building in the upper St. Marys River of the International Bridge and approaches in 1888, of cutting off from the rapids the flow through spans 1 and 2 of this bridge from the American shore by the Chandler-Dunbar Water Power Company in 1892, and

of building the compensating works immediately above the bridge, on the Canadian side, by the Michigan Lake Superior Power Company in 1901, has raised the monthly mean level of Lake Superior approximately 1 foot (0.966) in August, 1904. Owing to diversions of water at Sault Ste. Marie for power and other purposes, this effect is less by about 0.4 foot than the computed ultimate rise due to these obstructions. Since January, 1905, when the Michigan Lake Superior Power Company began to divert approximately 8500 cubic feet per second of water from the river for power purposes, the difference between the actual and original efflux stages has decreased to approximately 0.6 foot, a loss in level between 1904 and 1907 of 0.4 foot. Under original efflux conditions, the monthly mean level of Lake Superior would have fallen from 601.02 to 600.76, in April, 1892; from 601.01 to 600.82, in February, 1893; from 601.46, to 600.92, in March, 1898, and from 601.88 to 601.02, in March, 1903. The annual mean stage of Lake Superior, for 1904, would have been 601.84 under original conditions, while it was 602.71 under actual conditions. This artificial storage of water, due to the obstructions at the controlling section of the upper St. Marys River, partly explains why the stage of Lake Superior has been gradually rising while the stages of the lower lakes have not followed the same general upward trend.

145. The storing of water in Lake Superior has had its effect on the stage of the lower lakes. An increase in the transmitted supply from Lake Superior raises the stage of Lake Michigan-Huron an amount equal to the increase divided by the increment of discharge through the St. Clair River. The amount of additional water from Lake Superior that would have flowed into Lake Michigan-Huron between December, 1888, and December, 1904, is equivalent to the decrease in storage on Superior. This quantity represents a slice 0.87 foot thick over the entire surface of Lake Superior, equivalent to an average monthly increase in discharge of 1530 cubic feet per second through the St. Marys River between December, 1888, and December, 1904, inclusive. Under actual conditions this increase in discharge would not be a constant quantity but would change according to the effect of the obstruction or the diversion. Plate 27 shows a comparison of the monthly mean water levels of Lake Michigan-Huron under actual and original efflux conditions of the St. Marys River. The effect of storing water in Lake Superior by cutting off of spans 1 and 2 of the International Bridge at Sault Ste. Marie, in 1892, by the Chandler-Dunbar Water Power Company, was to lower

Lake Michigan-Huron by about 0.15 foot in 1894 and 1895. In 1896, the Lake Superior Power Company began to use water for power purposes on a large scale, which partially counteracted the effect of the obstructions. In 1902, the effect of the compensating works of the Michigan Lake Superior Power Company was to lower Lake Michigan-Huron by about 0.15 foot. In 1905 the Michigan Lake Superior Power Company began the diversion of water through their canal on the American side, which has, apparently, raised the stage of Lake Michigan-Huron about 0.1 foot, but in so doing it has been done at the expense of lowering Lake Superior by about 0.4 foot.

146. The effect on Lakes Erie and Ontario of the artificial storage of water in Lake Superior is slightly less than the effect on Lake Michigan-Huron. This decrease in effect is due to the increase in the increment of discharge of the outlets of Lakes Erie and Ontario. Plates 28 and 29 show a comparison of the monthly mean water levels of Lake Erie and of Lake Ontario, respectively, under actual and original efflux conditions of St. Marys River. While the effect of the cutting off of the flow through spans 1 and 2 from the rapids of the St. Marys River occurred about December, 1892, it was not materially felt on Lake Michigan-Huron until the latter part of 1893; not in Lake Erie until the middle of 1894, and not in Lake Ontario until the end of 1894. The effect of the construction of the compensating works at Sault Ste. Marie by the Michigan Lake Superior Power Company is also noticeable on these lakes. All the other changes in stage on Lake Michigan-Huron are faithfully reproduced on the stage of Lakes Erie and Ontario, the only difference being that they occur a little later and the effect becomes slightly less on each lake lower in the series. Where the maximum effect on Lake Michigan-Huron was about 0.15 foot, it was about 0.12 foot on Lake Erie, and about 0.10 foot on Lake Ontario.

147. The artificial storage of water in Lake Superior between December, 1888, and December, 1907, inclusive, by the placing of obstructions in the upper St. Marys River, has had the effect of raising the mean stage of Lage Superior by about 0.87 foot in 1904, and of lowering Lake Michigan-Huron, Lake Erie, and Lake Ontario by a maximum of 0.15, 0.12, and 0.10 foot, respectively. This hydraulic experiment, which has been carried on since 1888, shows that the use of Lake Superior as a storage reservoir can not be successful

if navigation is to be maintained unimpaired on Lake Superior and the St. Marys River.

REGULATION OF LAKE MICHIGAN-HURON.

148. To regulate the level of Lake Michigan-Huron near some fixed plane of reference would require regulating works at or near the head of the St. Clair River. The storage in the lake, that occurs in the first part of the year, could then be discharged through these works, while the outflow from the lake during the last half of the year could be diminished by an amount equal to the negative storage. An examination of Table 28 and Plate 18 shows that the monthly mean total supply to Lake Michigan-Huron for an average year has been as great as 237700 cubic feet per second, in May, and as small as 96200 cubic feet per second, in November. Plates 7 and 6 show that the maximum and minimum monthly mean total supply has been 470800 cubic feet per second, in June, 1883, and —32000 cubic feet per second, in September, 1871, respectively. The maximum monthly mean discharge from this lake, which occurred in July, 1883, has been determined as 275400 cubic feet per second. On the basis of the above extremes for total supply, to accomplish perfect regulation of this lake would necessitate provision for a maximum outflow of 470800 cubic feet per second, and a minimum of —32000 cubic feet per second. This required maximum outflow is 195400 cubic feet per second, or 71 per cent., greater than the actual maximum. If the outflow from Lake Michigan-Huron had been entirely shut off in September, 1871, the lake would still have fallen about 0.07 foot during that month. For the period of five months, August to December, 1871, inclusive, the average outflow from Lake Michigan-Huron, with perfect regulation, would have been only 43500 cubic feet per second; likewise, for the period of five months, August to December, 1894, inclusive, and for the months of September, October, and November, in the low-water year of 1895, the average outflow with perfect regulation would have been only 71700 and 46600 cubic feet per second, respectively. On account of the small quantity of water that would have flowed in the St. Clair and Detroit rivers during these three periods, the stage of these rivers, of Lake St. Clair and of Lake Erie would have been lowered several feet below the lowest known monthly water levels, and present navigation on the Great Lakes, below Lake Michigan-Huron, would have been entirely suspended.

149. These examples that have been cited show that the perfect regulation of Lake Michigan-Huron at a fixed plane of reference is not feasible even if it were possible to predict the quantity of water that nature would supply to any lake in any month.

150. The discharges of the St. Clair and Detroit rivers during the navigation season are comparitively uniform owing to the effect of the increased slopes in the rivers counteracting the effect of the decreased stages in the lakes. With the regulation of Lake Michigan-Huron, the discharge would be greatly increased during April, May, June, and July, and greatly decreased during August, September, October, and November. The latter are the critical months for the navigators. Any change in the flow of these two rivers, whereby the fluctuation in discharge would be increased, would prove a detriment to navigation.

151. Granting that the regulation of Lake Michigan-Huron could be accomplished by artificial works, the effect on the stage of water in the St. Clair River, Lake St. Clair and Detroit River would be so serious that any benefit derived from the increased depths in Lake Michigan-Huron would be more than offset by the decreased depths in the St. Clair River, Lake St. Clair, Detroit River, and the western end of Lake Erie.

152. At the present time, the stage of Lake Michigan-Huron is partially regulated by natural agencies. Nearly every winter, nature forms a regulating works in the St. Clair or Detroit river. These works consist of ice gorges, which retard the outflow from Lake Michigan-Huron, thereby storing water to be let out during the navigation season when it is so greatly needed in the lakes and connecting channels below Lake Michigan-Huron.

REGULATION OF LAKE ONTARIO.

153. To control the stage of Lake Ontario near some fixed level, regulating works could be constructed at the head of the Galop Rapids in the St. Lawrence River. These works would control the outflow from Lake Ontario and maintain the levels of the lake within definite limits. For perfect regulation, the storage in the lake must be discharged during the first half of the year and the outflow must be diminished by the amount of the negative storage during the last half of the year. An examination of Table 28 and Plate 18, shows that, for an average year, the monthly mean total supply to Lake Ontario has fluctuated between 297500 cubic feet per

second, in May, and 225500 cubic feet per second in January, while the monthly mean outflow has varied from 283600 cubic feet per second, in July, to 219300 cubic feet per second, in February. The maximum monthly mean total supply has been as large as 382400 cubic feet per second, in April, 1870, and as small as 154100 cubic feet per second, in February, 1875, while the maximum monthly mean discharge has been as large as 351200 cubic feet per second, in May, 1862, and as small as 152200 cubic feet per second, in February, 1902. In order to accomplish perfect regulation without enlarging the river cross section, the stage of Lake Ontario must be held at such a level that the outflow can be as great as 382400 cubic feet per second, or 31200 cubic feet per second greater than the maximum discharge to date. This required maximum outflow is only 9 per cent. greater than the actual maximum. For the low-water year of 1895, the average total supply was 185700 cubic feet per second, while the average outflow was 191600 cubic feet per second. If the oscillations in the levels of Lake Ontario are to be decreased without exceeding the extreme high water of 248.95, then the level of the lake should be held at such a stage that it will never exceed this maximum limit in months of excessive supply. Two consecutive months of excessive supply occurred in April and May of 1862, when the water-yield was 375600 and 372000 cubic feet per second, respectively. The outflow through the St. Lawrence River at regulated stage 248.95 would be about 350500 cubic feet per second. With a maximum discharge through the regulating works, there would still have been an excess in supply of 25100 and 21500 cubic feet per second, corresponding to a rise in lake surface of 0.33 foot, in April, and 0.28 foot, in May, or a total of 0.61 foot in the two months. Hence, if the level of the lake, under regulation, were allowed to fall 0.6 foot, or to 248.35, after the close of the season of navigation, then the plane of regulation of Lake Ontario would probably never be exceeded.

154. Regulating works, designed to discharge about 150000 cubic feet per second, as a minimum, and 350500 cubic feet per second, as a maximum, could be located at the head of the Galop Rapids and would control the monthly mean level of Lake Ontario between 246.95 and 248.95, a range of 2 feet. This scheme of regulation would reduce the fluctuations in lake level from 5½ feet to within 2 feet, and would raise the mean level of Lake Ontario about 2 feet.

155. The effect on the stage of water in the St. Lawrence canals with this scheme of regulation of Lake Ontario

would be to cause higher water in the first part and lower water in the last part of the navigation season. Such results would injuriously affect navigation.

COMPENSATING WORKS IN THE NIAGARA RIVER.

156. Your committee had hoped to present a discussion of a project for compensating Lake Erie for the loss of level due to diversions, by works placed above the rapids approaching Niagrara Falls. A preliminary examination, however, revealed a lack of data, which prevents consideration of the question at this time.

Authority, U. S. Lake Survey, except for supplied values.

a.—Gage readings taken at Superior, Wis.

b.—Supplied by applying to the mean reading, for the following or preceding month, the mean rise or fall in stage between such months for the years 1861 or 1862 to 1871, inclusive.

c.—Supplied by adding to the Sault Ste. Marie readings the mean fall in the water surface between Marquette and Sault Ste. Marie for the years 1871 to 1898, inclusive.

d.—Supplied in like manner from years 1899 to 1901, inclusive.

e.—From self-registering gage.

NOTE.—Elevations depend on zero of gage 601.75 ft. and B. M. 3,009.91 ft., U. S. Lake Survey, 1903 Levels.

TABLE 3.

WATER LEVELS OF ST. MARYS RIVER.

Monthly mean elevations of water surface of St. Marys River, at Southwest pier (above the locks) Sault Ste. Marie, Mich., in feet above mean tide at New York.

Authority, U. S. Lake Survey, except for supplied values.

a.—Values supplied by subtracting from the Superior, Wis., readings the mean fall in water surface between Superior and Sault Ste. Marie for the years 1860 to November, 1870, inclusive.

b.—From self-registering gage.

Note.—Elevations depend on B. M. "A" 606.089 ft., U. S. Lake Survey, 1903 Levels.

Authority, U. S. Lake Survey, except for supplied values.

a.—Supplied from Harbor Beach readings for the summer months, April to December, inclusive, by formula (G. T. R.—578)—0.880 (Harbor Beach—578)—0.530; and for winter months January to March, inclusive, by formula (G. T. R.—578)—0.880 (Harbor Beach—578)—0.235.

b.—Self-registering gage.

Note.—Elevations depend on B. M. Fort Gratiot Light-house (1877) as 860.343 ft., U. S. Lake Survey, 1903 Levels.

Authority, U. S. Lake Survey, except for supplied values.

a.—Deduced by subtracting 0.67 foot from St. Clair Flats values (U. S. L. S. Report, 1904), to obtain original values at Old Detroit Water Works, then supplying by formula (Fall St. Clair Flats to Amherstburg) — 0.9878 (Fall Old Detroit Waterworks to Amherstburg) + 0.883.

b.—Supplied by formula (Fall St. Clair Flats to Amherstburg) — 1.0357 (Fall Light-house Depot to Amherstburg) + 0.377.

c.—Supplied by using mean of two values derived from equations (Fall St. Clair Flats to Amherstburg) — 0.9878 (Fall Old Detroit Waterworks to Amherstburg) + 0.883; and (Fall St. Clair Flats to Amherstburg) — 1.0357 (Fall Light-house Depot to Amherstburg) + 0.377.

d.—Supplied by formula (Fall St. Clair Flats to Amherstburg) — 0.9878 (Fall Old Detroit Waterworks to Amherstburg) + 0.883.

e.—Derived by first subtracting 0.477 foot from New Detroit Waterworks' readings and then applying the mean monthly fall from St. Clair Flats to New Detroit Waterworks, as deduced from observations taken at those points from January, 1899, to June, 1901, inclusive.

f.—Derived from observations taken at Windmill Point by applying the mean monthly fall from St. Clair Flats Canal to Windmill Point as determined from simultaneous observations taken at those points from January, 1897, to July, 1907, inclusive.

Note.—Elevations depend on zero of gage 573.36 ft., and P. B. M., "Upper Light," 581.76 ft., U. S. Lake Survey, 1903 Levels.

TABLE 8.

Authority, U. S. Lake Survey, except for supplied values.

a.—Supplied by applying to the Cleveland, O., readings, the mean monthly rise or fall between Cleveland, O., and Buffalo, N. Y., from June, 1899, to December, 1906, inclusive.

b.—Derived from U. S. Lake Survey tables by subtracting 0.1 foot from records there given.

c.—Self-registering gage.

Note.—Elevations depend on B. M. "Light-house," 580.101 ft., U. S. Lake Survey, 1903 Levels.

Authority, U. S. Lake Survey.

e.—Self-registering gage.

Floods in Oswego River during the spring may cause abnormal gage readings from 0.2 to 0.3 foot above the true mean stage of Lake Ontario.

Note.—Elevations depend on zero of gage, 244.13 ft., and B. M. "A", 251.90 ft., U. S. Lake Survey, 1903 Levels.

Note—21, 24 and 27 indicate that St. Lawrence River discharges were derived from gage observations taken at Locks 21, 24 and 27, respectively.

WILLIAMS EXHIBIT 34.

CONSISTING OF

A series of Tables, Charts and Plates based on Williams Exhibits 1 to 33 incl., and 35 in this case, and the Records of United States Lake Survey, Reports of the Chief of Engineers, U. S. A., of the United States Geological Survey and of the United States Weather Bureau; and of Officials of certain States and Municipalities.

Compiled under the direction of
GARDNER S. WILLIAMS.

Continuation from Williams Exhibit 5 consisting of private data, Federal Office and Commission data.

Observations at Chicago 1871-1884 inclusive are from Chicago Weather Service Report, 1884, p. 5.

Observations at Chicago 1885-1891 inclusive are from Chicago Weather Service Report, 1891, p. 5.

Observations at Chicago 1892-1911 inclusive are from Chicago Weather Service Report, 1911, p. 5.

Observations at Chicago 1912-1916 inclusive are from Chicago Weather Service Report, 1916, p. 5.

Observations at Chicago 1917-1919 inclusive are from Chicago Weather Service Report, 1919, p. 5.

Observations at Chicago 1920-1922 inclusive are from Chicago Weather Service Report, 1922, p. 5.

Observations at Chicago 1923-1924 inclusive are from Chicago Weather Service Report, 1924, p. 5.

Observations at Chicago 1925-1926 inclusive are from Chicago Weather Service Report, 1926, p. 5.

Observations at Chicago 1927-1928 inclusive are from Chicago Weather Service Report, 1928, p. 5.

Observations at Chicago 1929-1930 inclusive are from Chicago Weather Service Report, 1930, p. 5.

Observations at Chicago 1931-1932 inclusive are from Chicago Weather Service Report, 1932, p. 5.

Observations at Chicago 1933-1934 inclusive are from Chicago Weather Service Report, 1934, p. 5.

Observations at Chicago 1935-1936 inclusive are from Chicago Weather Service Report, 1936, p. 5.

Observations at Chicago 1937-1938 inclusive are from Chicago Weather Service Report, 1938, p. 5.

Observations at Chicago 1939-1940 inclusive are from Chicago Weather Service Report, 1940, p. 5.

Observations at Chicago 1941-1942 inclusive are from Chicago Weather Service Report, 1942, p. 5.

Observations at Chicago 1943-1944 inclusive are from Chicago Weather Service Report, 1944, p. 5.

Observations at Chicago 1945-1946 inclusive are from Chicago Weather Service Report, 1946, p. 5.

Observations at Chicago 1947-1948 inclusive are from Chicago Weather Service Report, 1948, p. 5.

Observations at Chicago 1949-1950 inclusive are from Chicago Weather Service Report, 1950, p. 5.

Observations at Chicago 1951-1952 inclusive are from Chicago Weather Service Report, 1952, p. 5.

Observations at Chicago 1953-1954 inclusive are from Chicago Weather Service Report, 1954, p. 5.

Observations at Chicago 1955-1956 inclusive are from Chicago Weather Service Report, 1956, p. 5.

Observations at Chicago 1957-1958 inclusive are from Chicago Weather Service Report, 1958, p. 5.

Observations at Chicago 1959-1960 inclusive are from Chicago Weather Service Report, 1960, p. 5.

Observations at Chicago 1961-1962 inclusive are from Chicago Weather Service Report, 1962, p. 5.

Observations at Chicago 1963-1964 inclusive are from Chicago Weather Service Report, 1964, p. 5.

Observations at Chicago 1965-1966 inclusive are from Chicago Weather Service Report, 1966, p. 5.

Observations at Chicago 1967-1968 inclusive are from Chicago Weather Service Report, 1968, p. 5.

Observations at Chicago 1969-1970 inclusive are from Chicago Weather Service Report, 1970, p. 5.

Observations at Chicago 1971-1972 inclusive are from Chicago Weather Service Report, 1972, p. 5.

Observations at Chicago 1973-1974 inclusive are from Chicago Weather Service Report, 1974, p. 5.

Observations at Chicago 1975-1976 inclusive are from Chicago Weather Service Report, 1976, p. 5.

Observations at Chicago 1977-1978 inclusive are from Chicago Weather Service Report, 1978, p. 5.

Observations at Chicago 1979-1980 inclusive are from Chicago Weather Service Report, 1980, p. 5.

Observations at Chicago 1981-1982 inclusive are from Chicago Weather Service Report, 1982, p. 5.

Observations at Chicago 1983-1984 inclusive are from Chicago Weather Service Report, 1984, p. 5.

Observations at Chicago 1985-1986 inclusive are from Chicago Weather Service Report, 1986, p. 5.

Observations at Chicago 1987-1988 inclusive are from Chicago Weather Service Report, 1988, p. 5.

Observations at Chicago 1989-1990 inclusive are from Chicago Weather Service Report, 1990, p. 5.

Observations at Chicago 1991-1992 inclusive are from Chicago Weather Service Report, 1992, p. 5.

Observations at Chicago 1993-1994 inclusive are from Chicago Weather Service Report, 1994, p. 5.

Observations at Chicago 1995-1996 inclusive are from Chicago Weather Service Report, 1996, p. 5.

Observations at Chicago 1997-1998 inclusive are from Chicago Weather Service Report, 1998, p. 5.

Observations at Chicago 1999-2000 inclusive are from Chicago Weather Service Report, 2000, p. 5.

Observations at Chicago 2001-2002 inclusive are from Chicago Weather Service Report, 2002, p. 5.

Observations at Chicago 2003-2004 inclusive are from Chicago Weather Service Report, 2004, p. 5.

Observations at Chicago 2005-2006 inclusive are from Chicago Weather Service Report, 2006, p. 5.

Observations at Chicago 2007-2008 inclusive are from Chicago Weather Service Report, 2008, p. 5.

Observations at Chicago 2009-2010 inclusive are from Chicago Weather Service Report, 2010, p. 5.

Observations at Chicago 2011-2012 inclusive are from Chicago Weather Service Report, 2012, p. 5.

Observations at Chicago 2013-2014 inclusive are from Chicago Weather Service Report, 2014, p. 5.

" 3,4,5	573.88	3.32		2.66	573.47				41222

To interpolate Ouellette (1) and (2)
Mean fall Mamajuda to Amherstburg Apr. 24 to May 20
= 574.29-572.99 = 1.30

By statement of Report of C.Y. Dixon p. 11, the fall from Ouellette's to Amherstburg = 1.14
Fall Mamajuda to Ouellette = $\frac{16}{130}$ Mamajuda to Amherstburg

Gaging 1 M = Mamajuda, A = Amherstburg, O = Ouellette
M-A = 574.35-572.87 = 1.48
$1.48 \times \frac{16}{130} = 0.182$ ∴ Ouellette = 574.35-0.18 = 574.17

Gaging 2
M-A = 574.72-573.55 = 1.17
$1.17 \times \frac{16}{130} = 0.14$ ∴ Ouellette = 574.72-0.14 = 574.58

To interpolate Ouellette (5) S = Section
By 3 O-A = 573.83-573.10 = 0.73
S-A = 573.69-573.10 = 0.59
O-A = $\frac{73}{59}$ S-A = 1.237

By 4 O-A = 573.57-572.78 = 0.79
S-A = 573.43-572.78 = 0.65
O-A = $\frac{79}{65}$ S-A = 1.216

Mean (O-A)+(S-A) = 1.226
By 5 S-A = 572.84-572.10 = 0.74
∴ Ouellette's = 0.74 × 1.226 + 572.10 = 573.01

Williams Ex. 34. Chart I

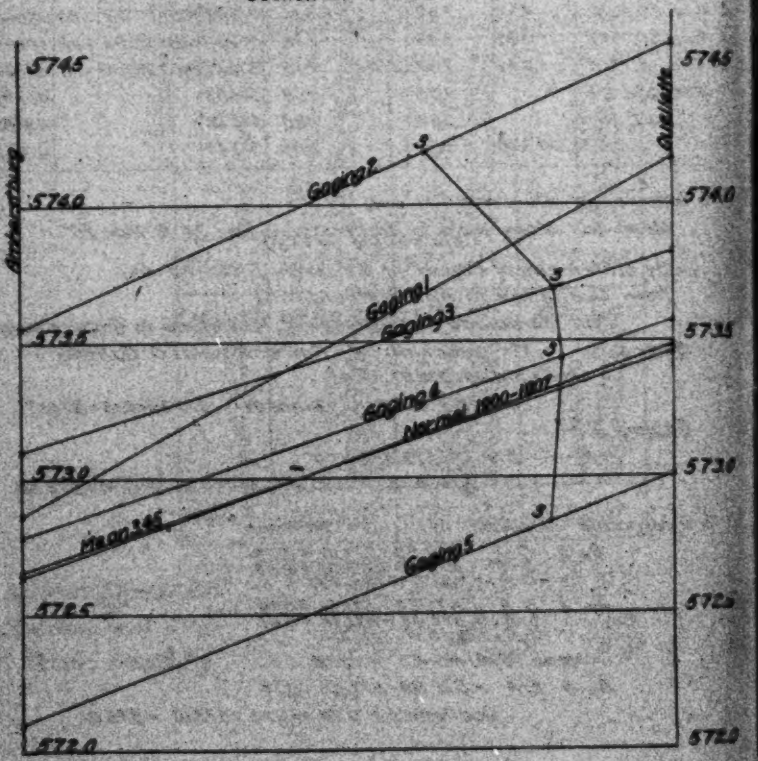
Chicago Sanitary District
Discharge of Lower Detroit River
Gage Relations

Mean St Clair Flats (1900-1907 Open Season) = 575.43
Amherstburg . . . . . = 572.65

$$\frac{\text{Fall St Clair Flats to Ouellette}}{\text{Fall St Clair Flats to Amherstburg}} = 0.703$$

$$\frac{575.43 - \text{Ouellettes}}{575.43 - 572.65} = 0.703$$

Ouellettes = 573.48



Williams Ex 34 *Chart III*

Dec 17	573.10	572.35	0.75	572.73	500	11883	23.77	2.93	34,838
Normal	573.48	572.65	0.83	573.07	500	12053	24.11	3.103	37,400

$$\frac{V_{normal}}{V_{mean}} = \left[\sqrt{\frac{0.83}{0.75}} = 1.052\right]\left[\sqrt{\frac{24.11}{23.77}} = 1.007\right] = 1.059$$

$V_{normal} = 1.059 \times 2.93 = 3.103$

$Q = 3.103 \times 12053 = 37,400$ c.f.s.

$S = O - \frac{17}{17}(O-A) = 573.48 - \frac{17}{17} \times 0.83 = 573.48 - 0.41 = 573.07$

Williams Ex. 34. *Chart VI*

Chicago Sanitary District

Discharge of Lower Detroit River

Lime Kiln Channel

1912

	Gualette	Anderson	Fall	Section	w	A	$\frac{A}{w}$	V	Q
Dec. 18	572.95	572.17	0.78	572.58	2670	38840	14.55	2.55	99128
Normal	573.48	572.65	0.83	573.09	2670	40282	15.06	2.67	107,339
Oct. 24	573.02	572.06	0.96	572.56	2670	38787	14.51	2.76	106,975
Normal	573.48	572.65	0.83	573.08	2670	40175	15.05	2.61	104,857

Mean for Normal = 106,098

(Dec. 18)

$$\frac{V_{normal}}{V_{mean}} = \left[\sqrt{\frac{0.83}{0.78}} = 1.031\right]\left[\sqrt{\frac{15.06}{14.55}} = 1.017\right] = 1.048$$

$$V_{normal} = 1.048 \times 2.55 = 2.67$$

$$Q = 2.67 \times 40282 = 107,339 \text{ c.f.s.}$$

(Oct. 24)

$$\frac{V_{normal}}{V_{mean}} = \left[\sqrt{\frac{0.83}{0.96}} = .930\right]\left[\sqrt{\frac{15.05}{14.51}} = 1.018\right] = .947$$

$$V_{normal} = .947 \times 2.76 = 2.610$$

$$Q = 2.610 \times 40875 = 104857 \text{ c.f.s.}$$

Dec. 18 $S = O - \frac{11}{12}(O - A) = 573.48 - \frac{11}{12} \times 0.83 = 573.48 - 0.39 = 573.09$

Oct. 24 $S = O - \frac{11}{12}(O - A) = 573.48 - \frac{11}{12} \times 0.83 = 573.48 - 0.40 = 573.08$

CHARACTERISTICS OF CUP AND SCREW CURRENT METERS; PERFORMANCE OF THESE METERS IN TAIL-RACES AND LARGE MOUNTAIN STREAMS; STATISTICAL SYNTHESIS OF DISCHARGE CURVES.*

BY B. F. GROAT, ASSOC. M. AM. SOC. C. E.

WITH DISCUSSION BY MESSRS. W. G. PRICE, E. E. HASKELL, CHARLES H. MILLER, JOHN C. HOYT, C. W. STANIFORD, AND B. F. GROAT.

During the summer and autumn of 1911 the writer ran a number of efficiency tests on two of the 6,000-h. p. hydraulic turbine units recently installed in the power-house of the St. Lawrence River Power Company, at Massena, N. Y. On one of the units, two sets of tests were run, one prior, and one subsequent, to cutting off several feet of the draft-tubes. On the other unit, one set of tests was run after the draft-tubes had been shortened, as had been done in the case of the other turbine unit.

In all, about 40,000 instrumental readings, including gauge readings, were made. Of these, 7,000 were complete velocity observations by current meters, and 4,000 additional readings on a Pitot tube furnished about 100 complete velocity observations for comparison with simultaneous readings by the current meters.

Owing to the nature of the tail-races, which discharge into the Grasse River, a weir test was out of the question. Before beginning the tests, therefore, it became necessary to decide between the current meter and Pitot tube as instruments for measuring the flow.

*Presented at the meeting of February 5th, 1913.

In favor of the current meter is its simplicity and the f
cility with which it may be used in tail-races. Against it
the fact that, notwithstanding the large number of observe
who have experimented with it and the large number of re
ords which have been made by it, there is still a great deal
well-founded skeptical discussion as to the accuracy of t
instrument when the records are based solely on the sti
water rating.

The Pitot tube has been not only a subject of adverse cr
cism but also an instrument about which much positive i
norance seems to exist. It would seem, however, that t
recent demonstrations of the accuracy of Darcy and Basi
experiments, 1865, by Messrs. William Monroe White,* F
F. Moody, Gardner S. Williams, John R. Freeman, and other
should sufficiently dispel all doubts as to the reliability
the instrument. On the other hand, where the velocity of t
water is variable from moment to moment, a large number
readings must be taken and reduced to a mean square roo
in order to obtain sufficiently close approximations to th
average in any one velocity determination.

After a final summary of advantages and disadvantage
it was decided to use both the screw and cup types of curre
meter, and to check their records, if necessary, with a Pit
tube.

E. E. Haskell, M. Am. Soc. C. E., Director of the College o
Civil Engineering Cornell University, made up one of h
screw type meters especially for the series of tests to be u
dertaken, and a new Gurley-Price meter of the cup type (No
600) was purchased from the makers at Troy. Master Me
chanic D. J. Jones, of the Power Company, made up a Pito
tube, following as nearly as possible the description of Tub
N given in Mr. White's paper, mentioned above.

The following are the general conclusions concerning cu
rent meters which have been drawn from the tests with th
foregoing equipment:

1.—†When a cup meter is run in perturbed water it wi
register a larger number of revolutions per second than
perfect still-water rating would indicate.

2.—†When a screw meter is run in pertubed water it wi
register a smaller number of revolutions per second than
perfect still-water rating would indicate.

---

*"The Pitot Tube: Its Formula," by William Monroe White, *Jour*
Association of Engineering Societies, Vol. XXVII, 1901, p. 35.

For other reference marks see following page.

3.—†In the foregoing sense, a cup meter is affected relatively to a much greater extent than a screw meter. In the tail-races at Massena, as an average, the cup meter was affected to the extent of 6%, while the Haskell meter was affected mostly by less than 1 per cent. In boilers of considerable violence the cup meter may easily over-register by 25%, while the screw meter will under-register by not more than 3 or 4 per cent.

4.—Either type of meter when run in perturbed water will give uniform records in equal times, provided these times are sufficiently long, the flow of the water itself being subject to an established regimen.

5.—If both types of meter are used simultaneously in perturbed water, the disparity between the discrepant velocities thus determined by the still-water rating may be taken as a basis for correcting the discrepant velocities.

6.—The average corrections thus obtained for the Haskell meter when run with the Gurley-Price meter in the tail-races at Massena varied from 0.5 to 0.9 of 1%, while the corresponding corrections for the Gurley-Price meter were about six times larger. Comparisons with the Pitot tube furnished substantially the same corrections as those obtained by comparison of the meters.

7.—It would seem to follow that current-meter observations based on still-water ratings without further correction should

---

†In a discussion of a paper on current meter and weir discharge comparisons by Edward C. Murphy, Assoc. M. Am. Soc. C. E. *Transactions*, Am. Soc. C. E., Vol. XLVII, 1902, p. 370, Charles H. Miller, M. Am. Soc. C. E., describes certain experiments on screw and cup meters in the following language:

"The Haskell meter was lowered from one side of the skiff and one of the Price meters from the other side, both to the same depth (about 5 ft.). The registrations or revolutions of each, for periods of from 5 to 10 minutes, were noted; then, for similar periods of time, the skiff was caused to rock from one side to the other at short intervals, and the registrations recorded, the movement of the skiff giving to the meters a vertical motion of from 1 to 2 ft. Under this motion the revolutions of the Price meter increased, while those of the Haskell meter decreased, but in a less proportion than the increase of the Price meter, showing that the error due to instability of support is greater in the Price than in the Haskell meter. Lack of time prevented more extended observations, and in different velocities of current, which probably would have evolved some fixed difference due to the different construction of the meters in question."

Conclusions 1, 2 and 3, of the present paper seem to have been fairly stated by Mr. Miller, but as applied only to instability of support. They are here advanced as inherent characteristics of these different types of meter, and extended to apply, not only to cases of instability of support, but also to these current meters generally, however supported, in flowing water.

be made with great caution. On the other hand, it seems certain that the correction for a cup meter when run at a good meter station on an open river is not large, while the corresponding correction for a screw meter may be negligible.

Plate XXIII shows the results of a number of ratings of the Haskell meter. The general method was similar to that adopted by the United States Lake Survey, as described in the reports by F. C. Shenehon, M. Am. Soc. C. E.,* covering his current-meter observations. The meter was suspended either by cable or rod from a bowsprit at the head of a light skiff. The skiff, with an observer, was then towed back and forth over a 200-ft. base at a given velocity, one such double run constituting a velocity observation. The total time and total number of revolutions then stand for the transit of a 400-ft. base in perfectly still water.

The first four ratings, on June 29th and 30th, 1911, were made along the longitudinal center line of Lock No. 15 in the old Cornwall Canal, at Cornwall, Ont. Both lock gates were open, but the north miter leaf of the lower gate, opening into the St. Lawrence River was not fully into its recess in the north wall. The meter was about 4 ft. below the surface of the water, and the depth in the lock was 9 or 10 ft. The water in the lock had a tendency to surge at times. Sometimes there was considerable velocity through the lock, and at other times very little.

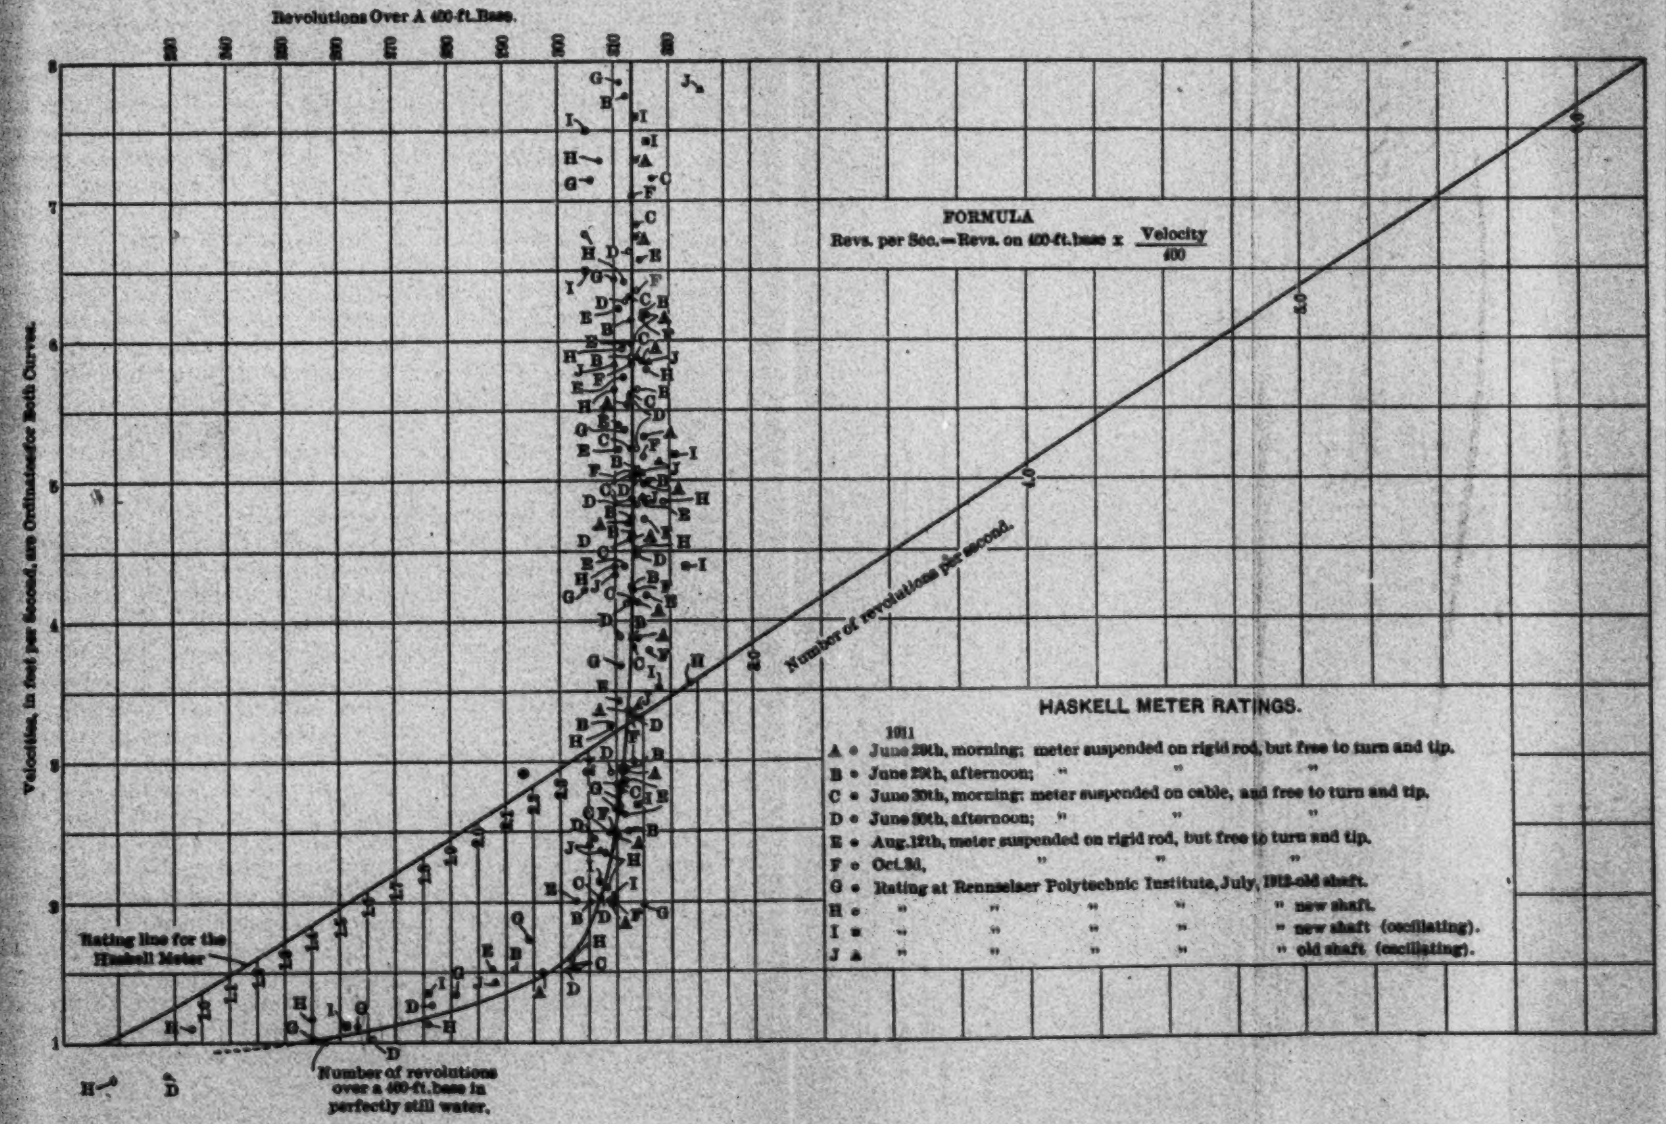
The ratings of August 12th and October 3d, 1911, were made in a bay of the Grasse River, opposite the power-house of the St. Lawrence River Power Company, at Massena, N. Y. The meter was about 2.25 ft. below the surface of the water, and the average depth under the base line was about 7 ft., with a shallow spot near the east end about 5 ft. deep. There was very little current, but at times there were surges due to the operation of the power-house just across the river.

The ratings of July, 1912, were made under the direction of Professor Arthur M. Greene, Jr., at the rating station of Rensselaer Polytechnic Institute, Troy, N. Y., after the meter had been used extensively at Massena and in North Carolina and Tennessee. The meter had been overhauled twice at Cornell University before these ratings, but long after those at Massena. The meter was also provided with a new shaft. After running a complete set of tests at Troy, the new shaft was put in and another set of tests was made.

---

*As described in Reports, Chief of Engineers, U. S. Army, 1900 to 1904, inclusive.

PLATE XXIII.
TRANS. AM. SOC. CIV. ENGRS.
VOL. LXXVI, No. 1289.
GROAT ON
CUP AND SCREW CURRENT METERS.



The curve of revolutions over a 400-ft. base was plotted from the first four ratings in the Cornwall Canal. It will be seen from Plate XXIII, however, that the subsequent ratings do not materially alter the position of this line, up to velocities of 5 or 6 ft. per sec. If the correction were made, the number of revolutions, as shown by the line, would be increased only ¼% at 4 ft. per sec., and reduced only ¼% at about 8 ft. per sec. In fact, it may be seen that, out of about 100 double runs in the canal lock and Grasse River, not one plotted point differs by more than 1% from the line of revolutions as determined from the first four ratings for velocities of more than 1½ ft. per sec. For velocities of less than 1½ ft. per sec. the line of revolutions is so steep that errors of somewhat larger magnitude are to be expected. In the oscillating tests, the meter was oscillated parallel to the motion of the car, and covered an amplitude of 5¾ in. for every 8-ft. advance of the car. Transverse oscillations reduce the number of revolutions over a given base. The relations between velocity and revolutions over a 400-ft. base were then plotted, as shown on Plate XXIII, and from the resulting curve the rating line for still water was located and drawn, also as shown on that plate.

After having drawn the rate line, a reduction diagram, Plate XXIV, may be prepared, from which velocities may be read directly when referred to time and revolutions. This obviates either the necessity for reducing revolutions to revolutions per second, or of taking a fixed time for observing velocities, which is inexpedient where velocities are variant.

Plate XXV shows the Gurley-Price meter rating curves, obtained in a manner precisely similar to that used for the Haskell meter. In fact, the ratings were frequently made on the same day as for the Haskell meter.

In order that there may be no misundertanding concerning these ratings, it may be stated that the tests were severe, when considered as a whole. Some of the ratings were made at a depth of 4 ft., some at a depth of 2 ft. 3 in., some in windy weather, some in calm weather, and several different observers acted at different times.

Under all these diverse conditions, it may be seen that the Haskell meter, in the Massena and Cornwall ratings, never varied by more than 1% in any individual observation, and that rating lines drawn for different ratings would differ by only 0.2 or 0.3 of 1% at the greatest.

The Gurley-Price meter exhibits a much greater range of

- August 15, A.M.
- September 20.

variations, 5 or 6% up to velocities of 5 ft. per sec., which were considerably in excess of the mean velocities in the tail-races where the meter was used.

It is not contended here that a satisfactory still-water rating under perfect conditions cannot be obtained with a meter of this type; it is intended, however, to show that varying conditions of water produce relatively larger variations in the records of the cup meter than in those of the screw meter.

On comparing the maker's rating curve with the several ratings in the canal and in the bay of Grasse River, it will be seen that the number of revolutions of the Gurley-Price meter over a 400-ft. base is generally higher in the canal and bay than in the maker's rating. Hence it is fair to suspect that a perfect still-water rating line of a cup meter is a line of minimum number of revolutions for such a meter, and that, when the water is disturbed in any degree, the number of revolutions over a fixed base will always be increased, other things being equal.*

Similarly, the contrary suspicion may be entertained, that a perfect still-water rating line of a screw meter is a line of maximum number of revolutions for such a meter, and that, when the water is disturbed in any degree, the number of revolutions over a fixed base will always be decreased, other things being equal.

Since, under similar circumstances, the deviations of the Gurley-Price meter are about six times as large as those of the Haskell meter, but in the contrary sense, it would seem fair to conclude that when the meters are run simultaneously in flowing water, one-seventh of any difference in the velocities thus determined from the still-water ratings should be attributed to a deviation of the Haskell meter, while six-sevenths should be attributed to a simultaneous deviation of the Gurley-Price meter.

Thus, if the difference between the velocities determined by the Haskell and Gurley-Price meters should be 0.42 ft. per sec., 0.06 ft. per sec. should be added to the record of the Haskell meter, while 0.36 ft. per sec. should be deducted from the corresponding record of the Gurley-Price meter. In strictness, this correction should be applied to revolutions per second, but, as the number of revolutions is so nearly proportional

*Certain interesting experiments by Professor L. F. Moody, in the rating station at Rensselaer Polytechnic Institute, seem to agree with the writer's experiments on this point and confirm the general conclusion.

to the velocity, and as the corrections are relatively small, no serious error results. The particular ratio here determined, of course, applies only to the two individual meters as used in the tail-races at Massena by the writer.

In order to establish more satisfactorily the principle mentioned above, the boat was rocked during several of the runs of a rating, imparting to the meter which was being rated an oscillation in an arc about 3 ft. long and about 2½ ft. in radius, and at right angles to the direction in which the meter was being drawn through the water. The result was that the Gurley meter was found to increase its number of revolutions by 15% while the Haskell meter reduced its number of revolutions by 2½%, practically the same ratio as that deduced above from the rating curves. The effect of longitudinal oscillations was tested also. The result of special tests of this character at Rensselaer Polytechnic Institute may be seen on Plate XXIII. Subsequently, other tests on a new Haskell meter showed that longitudinal oscillations of 22 in. in 6 ft. advance of car retarded the meter slightly, up to velocities of about 2 ft. per sec., above which the meter was accelerated, the error being less than 2% at 9 ft. per sec. The net result in perturbed water, however, seems to be slight retardation in all cases.

It is now desirable to show how these principles have been used to correct the current-meter records actually observed in the tail-races during the turbines tests referred to at the outset. In order to do this properly, it will be necessary to state another conclusion, based on the current-meter records, which the writer hopes to take up more fully in the future under another title. The conclusion is as follows:

Under an established regimen, the distribution of the flow of water in a tail-race obstructed by tilling racks is fixed in character, the ratio of the average velocity at any given point to that at any other given point in the race being constant. This proposition applies over a considerable range in the total amount of discharge, but supposes the actual wetted cross-section of the race to remain the same.

The foregoing proposition was proven from a number of the turbine tests by computing and compiling the relative velocities at the 84 meter points in the races where velocity observations were taken. A turbine unit discharged through two tail-races, each about 15 ft. wide, while the depth of the water varied from 15 to 16 ft. The meter section of each race was divided into six equal vertical, and seven equal horizontal

strips, and the meter points were the forty-two intersections of the median lines of the strips. The verticals were numbered 1 to 6 from west to east, while the depths were numbered 1 to 7 downward.

To demonstrate the truth of the principle of a fixed distribution of flow in tail-races, and also as a verification of Conclusion No. 4, Tables 1 to 4 are given:

TABLE 1—GURLEY-PRICE METER IN WEST RACE, SHOWING CONSTANCY OF VELOCITIES TAKEN IN QUICK SUCCESSION. VELOCITIES WERE OBSERVED WITH A SINGLE STOP-WATCH PROVIDED WITH TWO SECOND HANDS.

Test of September 9th, at 0.82 gate.
The numbers are of revolutions per second.

Depths.	Verticals.						Totals of lower set.
	1	2	3	4	5	6	
1	1.38	1.40	1.15	0.88	0.90	0.94	6.69
	1.36	1.43	1.16	0.89	0.87	0.95	
2	1.39	1.44	1.40	1.26	1.20	1.16	7.70
	1.34	1.44	1.40	1.24	1.22	1.16	
3	1.36	1.44	1.42	1.40	1.34	1.31	8.46
	1.36	1.44	1.39	1.41	1.35	1.31	
4	1.37	1.44	1.43	1.39	1.31	1.27	8.41
	1.36	1.44	1.43	1.39	1.32	1.26	
5	1.38	1.47	1.38	1.40	1.35	1.28	8.57
	1.40	1.46	1.38	1.40	1.37	1.28	
6	1.70	1.78	1.80	1.77	1.61	1.06	10.09
	1.66	1.78	1.80	1.78	1.60	1.06	
7	1.60	1.81	1.84	1.78	1.78	1.06	10.84
	1.66	1.80	1.84	1.78	1.79	1.06	
Totals of lower set.	10.07	10.74	10.75	9.76	9.58	9.64	60.56

The register was started first and the observer noted the pointer as it clicked from revolution to revolution of the meter. By synchronizing with the rythm of the register, it was possible for the observer to start the stop-watch almost exactly at the moment the register clicked to zero. Similarly, the primary second hand could be stopped after any desired number of revolutions while the secondary hand could be stopped at, say, twice that number. Thus, two or more velocities in immediate succession could be determined for each meter point in the tail-races.

In support of the principle of fixed distribution, it may be stated that the percentages corresponding to the figures of

Tables 1 and 2 at the 84 meter points agree remarkably well with the corresponding ones of Tables 3 and 4 after applying certain necessary small corrections. Tables 1 and 2 each represent an individual set of double discharge measurements in one of the races, while Tables 3 and 4 have been compiled as average percentages from a number of such sets of observations.

In Verification of Conclusion No. 4, it may be seen that each pair of velocities determined at the same point by either meter consists practically of two equal velocities. This truth has been found to apply throughout the turbine tests.

TABLE 2.—HASKELL METER IN EAST RACE, SHOWING CONSTANCY OF VELOCITIES TAKEN IN QUICK SUCCESSION. THE COMPARISONS ARE NOT AS GOOD AS WITH THE GURLEY-PRICE METER, BECAUSE THE VELOCITIES WERE TAKEN WITH TWO DIFFERENT WATCHES, ONE OF WHICH WAS NOT VERY RELIABLE.

Test of September 9th, at 0.82 gate.
The numbers are of feet per second.

Depths.	Verticals.						Totals of lower set.
	1	2	3	4	5	6	
1.....	3.75	3.74	3.68	3.61	3.94	3.75	
	3.73	3.75	3.80	3.80	3.97	3.73	17.40
2.....	3.68	....	....	....	....	....	
	3.67	3.69	3.86	3.97	3.76	4.01	21.40
3.....	4.13	3.96	3.92	3.91	4.13	4.09	
	4.08	3.99	3.78	3.98	4.17	4.10	24.34
4.....	4.21	3.98	3.94	3.77	3.98	4.07	
	4.03	3.95	3.94	3.70	3.91	4.05	23.45
5.....	4.09	3.90	3.73	3.68	3.91	4.03	
	4.05	3.94	3.73	3.67	3.94	4.20	23.27
6.....	4.17	4.00	3.74	3.61	4.13	4.44	
	4.30	4.01	3.73	3.68	4.13	4.49	24.35
7.....	3.97	3.97	3.86	3.85	4.06	4.01	
	3.93	3.97	3.86	3.91	4.06	4.01	23.37
Totals of lower set.	23.51	23.89	23.56	23.46	23.99	23.92	142.33

The two velocities at each meter point were taken in immediate succession in a manner similar to that described in the foot-note under Table 1, except that two stop-watches were used. The observations were about 1 min. in duration for the first velocity and twice as long for the second velocity.

TABLE 3.—RELATIVE DISTRIBUTION OF FLOW IN WEST RACE OF UNIT NO. 3 DURING TESTS OF JULY AND AUGUST. WATER SURFACE AT ELEVATION 162.85.

Depths.	Verticals.						Totals.
	1	2	3	4	5	6	
1	2.16	2.16	1.84	1.88	1.80	1.97	11.10
2	2.11	2.41	2.32	2.07	2.02	2.22	13.15
3	2.04	2.37	2.46	2.21	2.15	2.14	13.30
4	2.13	2.30	2.34	2.20	2.05	2.36	13.53
5	2.19	2.41	2.37	2.20	2.27	2.07	14.40
6	2.05	2.37	2.00	2.05	2.42	2.05	16.47
7	2.72	2.37	2.00	2.00	2.00	2.00	17.70
Totals	16.00	17.40	17.53	16.21	15.66	17.06	99.96

The numbers are percentages of the sum of the velocities at the 42 meter points in the race. Thus, in Vertical 1, Depth 1, the velocity is 2.16% of the sum of all the velocities at the meter points.

TABLE 4.—RELATIVE DISTRIBUTION OF FLOW IN EAST RACE OF UNIT NO. 3 DURING TESTS OF JULY AND AUGUST. WATER SURFACE AT ELEVATION 162.85.

Depths.	Verticals.						Totals.
	1	2	3	4	5	6	
1	1.72	1.80	1.86	1.65	2.16	2.24	11.20

7	3.00	2.24	2.11	2.00	2.00	2.72	16.60
Totals	17.12	16.88	16.91	16.25	16.97	17.22	100.00

The percentages of Tables 3 and 4 are computed by dividing the velocity at any meter point by the sum of the velocities at all the meter points.

Attention should be directed to the fact that while water discharged from a turbine will be much quieted by stilling racks, yet the latter themselves are sources of disturbance, and that the violent agitation caused by the turbines is merely supplanted by an entirely different type of disturbance produced by the racks. The effect of the racks is to render the flow parallel to the side-walls of the race, but the body of the water is full of small eddies and boilers of more or less violence. The parallelism of flow at each meter point was tested by a kind of inverted weather vane, which the writer understands was first used by John R. Freeman, M. Am. Soc. C. E. The indications of parallelism of flow by this vane were extremely satisfactory at all points.

The meter section was about 30 ft. down stream from the racks. The effect of the disturbance from the racks, however, was plainly indicated by the divergence of the velocity records, based on the still-water ratings, when the two meters were run in quick succession at any meter point. It is well to note here that the velocity was greater near the bottom of the race than at the top, and that the agitation by the racks was greater near the top than at the bottom, where the flow was extremely steady and subject to little or no agitation. This is clearly shown by the records, and especially by the fact that the clicking of the register was almost absolutely uniform when the meters were near the bottom. It is also shown by the fact that there was always a greater disparity between the meter records near the surface than at the bottom.

To be precise, the corrections for the meters should be computed for each of the 84 meter points in the races. Practically, the corrections may be made for the average velocities in the seven horizontals, because the velocities along any horizontal do not vary widely.

An example of the computation of corrections for the Haskell and Gurley-Price meters is given in Table 5.

TABLE 5.—COMPUTATION OF VELOCITY CORRECTIONS.

Horizontal in which meter was run.	Velocities Based on the Still-Water Ratings.		Difference.	One seventh of difference + Haskell = true velocity.	Velocity excessive by Gurley. Percentage.	Velocity deficient by Haskell. Percentage.
	Gurley.	Haskell.				
1.....	3.04	3.26	0.22	3.04	14.5	2.4
2.....	4.40	4.50	0.10	4.50	12.0	2.0
3.....	4.74	4.44	0.30	4.46	5.8	0.96
4.....	4.66	4.62	0.04	4.66	4.3	0.72
5.....	5.08	4.89	0.19	4.98	3.1	0.55
6.....	5.09	5.35	0.13	5.37	2.0	0.34
7.....	6.29	6.75	0.17	6.17	2.3	0.39
Totals..	33.07	33.91	2.16	33.21		

$$\text{Average error of Gurley meter} = \frac{6}{7} \times \frac{2.16}{33.21} = 5.6 \text{ per cent.}$$

$$\text{Average error of Haskell meter} = \frac{1}{7} \times \frac{2.16}{33.21} = 0.93 \text{ " "}$$

The method given in Table 5 for computing the corrections for the velocities is based solely on the current-meter ratings and the rocking experiments in conjunction with the fundamental propositions before stated. It is desirable, therefore, to have independent means of checking the methods and the numerical results.

Accordingly, a Pitot tube was operated at the meter points, in Depths 2, 3, 5, 6, and 7, simultaneously with the Haskell meter. While the meter was recording in Vertical 3 the Pitot was recording in Vertical 2. After the record was taken, both the meter and Pitot were advanced to the next succeeding verticals, so that the meter would then record in Vertical 4 while the Pitot was in Vertical 3. Depths 1 and 4 were omitted because the tail of the Pitot was out of water in Depth 1, and the construction of the piping of the Pitot did not conform with the staging for the observers in such a way as to admit of readings in Depth 4. This might have been remedied, but no great importance was attached to these facts.

The results of these tests are given in Table 6.

It should be noticed in Table 6 that the velocities given in Verticals 1 and 6 were not taken in quick succession. The meter and tube were traversed across each horizontal, beginning with the Pitot tube in Vertical 1 and the meter in Vertical 2, and ending with the Pitot tube in Vertical 5 and the meter in Vertical 6. After the five horizontals were traversed in this manner, the Pitot tube and meter were interchanged in

relative position, and readings were taken at the five dept with the Pitot tube in Vertical 6 and the meter in Vertical All other readings by the meter or Pitot tube were follow immediately by a reading of the other instrument.

The writer does not wish to make too much of these Pi tube tests. The experimenters were not familiar with the i strument, as they had used it on only one other occasion. T dynamic and static columns were drawn up on a scale gra uated to single tenths and half tenths of a foot and the di ferences in head were merely estimated to the nearest hu dredths of a foot. This may seem crude, but when it is co sidered that the water columns are both vibrating, sometim violently, that twenty or thirty readings are taken for ea velocity, and that all percentage errors are nearly split two by the process of extracting the square root of the hea it will be seen that the method is probably as accurate as ne be for the purpose at hand. Indeed, the results seem to justi this conclusion.

Attention may be directed to three general facts shown the summary of Table 6. The ratios for the verticals increa toward the right in the west race. They increase toward t left in the east race. The ratios for the horizontals increa upward in both races. On the whole, the tendency is for th ratio of the Pitot velocity to the meter velocity to increase u ward, as it should, as it has been shown that the meter retarded toward the surface.

Remarks: *A*—tests in W. race at 0.7 gate; *B*—tests in E. race at 0.7 gate; *C*—tests in W. race at 0.87 gate.

It is not wholly clear to the writer, however, why the Pitot tube velocity should be in the neighborhood of 1½% less than the meter velocity at the greater depths. It is not improbable that this would have been partly compensated for, had the observations in the east race been continued to Depths 5 and 6, but probably not entirely. In fact, there seems to be a reciprocal relation, as noted above, between the readings in the two races. This would follow naturally, owing to the symmetry of the flow in the races as to the central dividing wall, and the fact that the meters always rotate in the same direction. Thus, if there is an eddy clockwise at a certain position in either race, there should be a symmetrically located eddy counter-clockwise in the other race, and these might have opposite effects on the meter, the Pitot tube not being affected in the same way.

It is not impossible that the Haskell meter was running a trifle faster near the bottom of the race than the actual still-water ratings would indicate that it should. This would result from the fact that the rating boat was not a rigid support, nor was the water absolutely still during the ratings. This would necessitate shifting the rate line of the Haskell meter toward its ideal position of a maximum number of revolutions. This, in turn, would diminish all discharge records based on still-water ratings. On the other hand, to be consistent, it would follow that the rate line of the Gurley-Price meter would have to be shifted toward the maker's rate line, which would make for a larger correction to be added to velocities by the Haskell meter when based on still-water ratings, thus leaving true velocities in Table 5 practically unchanged. In corresponding manner, all the ratios of Tables 6 and 7 would be increased, while the meter velocities would be less in the same proportion, the effect of which would be to leave the corrected true velocities corresponding to the tables unaltered, they being in fact those of the Pitot tube. Thus, discharge estimates would not be affected materially in either case. The most reasonable explanation, however, is that the Pitot tube itself is variously affected by small amounts in different parts of the raceways.

The object, however, is not to speculate on such matters, but simply to check the computation of a small correction to the velocity, which correction may be in error by 50% and yet not affect the discharge measurements by the meter by more than three or four tenths of 1 per cent.

Interpolating a percentage for Depth 1, which was not ob-

served in the tests, equal to the mean given for Depth 2, 1.055, and another in Depth 4, taking an average between the means for Depths 3 and 5, practically 1.000, there may be arranged the figures in Table 7.

TABLE 7.—AVERAGE CORRECTION FOR HASKELL METER, BASED ON COMPARISON OF CURRENT METER AND PITOT TUBE RECORDS.

Depths.	Ratio of velocity by Pitot tube to that by current meter, from Table 6.	Relative velocity in each horizontal, being a mean for Haskell meter.	Corrected relative meter velocity.
1.....	*1.055	10.30	10.76
2.....	1.055	11.98	12.51
3.....	1.001	13.50	13.51
4.....	*1.000	14.04	14.04
5.....	0.998	14.06	14.04
6.....	0.955	15.86	15.86
7.....	0.904	19.96	18.39
		100.00	100.61

*Interpolated velocity ratio.

It follows from Table 7 that an approximate correction of 0.61% should be applied to discharges determined by the Haskell meter when used in these tail-races, and basing velocities on the still-water rating.

As a matter of fact, no direct use whatever was made of the still-water rating curves of the Gurley-Price meter, except to compute the corrections for the meters, which seem to be substantially verified by the Pitot tube tests. In reality, the Gurley-Price meter was rated relatively to the Haskell by comparisons of the simultaneous records taken by the meters in the two races during the numerous turbine tests.

While the Haskell meter runs in the west race, the Gurley-Price meter runs in the east race, and *vice versa*. If a pair of turbine tests be selected where the conditions are substantially the same, the Haskell meter being in the west race during one of the tests and in the east race during the other test, the total sum of the 84 velocities by the Haskell meter may be plotted to the total sum of the 84 numbers of revolutions per second by the Gurley-Price meter. If a number of such points be plotted, the curve drawn through them will represent the functional relation between the sum of the 84 velocities by the Haskell meter and the corresponding total sum of the numbers of revolutions per second by the Gurley-Price meter at the 84 meter points in the two races.

- In races of No. 3 after cutting off Draft-Tubes.
- In races of No. 3 before cutting off Draft-Tubes.

METHOD OF COMPARISON. The sum of the numbers of revolutions of the Gurley meter at the 48 meter points in either race during any test, is reduced to correspond to the same area as the corresponding sum of the velocities by the Haskell meter by multiplying the number of revolutions of the Gurley meter by the inverse ratio of the areas of the two races. A pair of tests at the same gate is selected where the Haskell meter was in opposite races in the two cases. The half sum of the number of revolutions by the Gurley meter is then plotted to the half sum of velocities by the Haskell meter as indicated by the three classes of dots above. Curves may then be drawn as shown to distinguish the three cases.

As the two races are so nearly alike, it may be accepted that, on the average, half the total sum of the 84 velocities will correspond to half the total number of revolutions per second at the 84 meter points, as a functional relation between the total sum of the velocities at the 42 meter points and the corresponding total sum of the revolutions per second at these points for either race taken separately.

Plate XXVI is such a relative rating curve, compiled from selected turbine tests, and may be used to reduce the records of the Gurley-Price meter to what they would have been by the Haskell meter. Thus, if in any tests on Unit No. 5 the Gurley-Price meter makes a total sum of revolutions per second of 50, then, by this curve, the Haskell meter would have made a record indicating a sum of 149.3 ft. per sec.

It was not found necessary to have any regard for the individual velocity by the meter at any point, except as a part of the total sum. A system of constants and ratios was devised, so that, to obtain the mean velocity in a raceway during any tests, it was merely necessary to multiply the sum of the velocities at the 42 meter points by a factor obtained from a curve. This, however, is a matter which the writer hopes to take up more in detail at another time, and therefore, he will confine himself here to the performance of the meters in the tail-races.

With this relative rating curve and the percentages of Tables 3 and 4, it would be quite possible to determine the absolute rating curve of either meter at each of the 84 meter points; but this is hardly necessary. It will suffice here, as a matter of interest, simply to conclude this paper by determining what the average absolute rating curve of the Gurley-Price meter was in the turbine tests. This may be done by dividing the numerical value of the abscissas and ordinates of Plate XXVI by 42 and plotting the resulting pairs of reduced co-ordinates to the corresponding reference lines in Plate XXV.

It may there be seen that the number of revolutions per second by the Gurley-Price meter in the tail-races was, on the average, about 6% greater than the still-water rating would indicate. In other words, if the writer had relied on this meter alone, without any other guide than the still-water rating curve, his discharge results would undoubtedly have been 6% too high.

These conclusions are not to be taken as casting any reflections on the Gurley-Price meter, which according to the

writer's experience, is an admirably constructed instrument. In fact, the results could not have been obtained without it. The rating of the meter was perfectly definite at each of the 84 meter points in the races, but could not be determined directly by the still-water rating, which, in reality, is the only thing at fault. The still-water rating should never be applied without regard to the probable deviations of the speed of revolution due to disturbances in the water. An excellent check on the meters is to rate them where operated with a Pitot tube.

ADDENDA.

Since the foregoing was written, the writer has had a very instructive experience with several types of meter used simultaneously on a complicated network of mountain streams. The results of oscillating the meters have confirmed the general conclusion that in all cases, relatively, cups are accelerated considerably, while screws are retarded slightly, in turbulent water. The errors of the cup meter, based on still-water ratings, were from 3 to 6 times greater than those of the screw, and in the contrary sense.

Design of Meters.—The principal desideratum of a current meter is that it should give the resolved component of velocity in a direction fixed relatively to the meter. The fact that a cup over-registers in turbulent water while a screw under-registers, gives a basis of design which may be used to produce a meter possessing this characteristic more or less rigidly. If the blades of a screw are "cupped" to the proper extent, and in the right sense, the effect may thus be toward neutralizing the retardation which the screw would otherwise suffer.

There are other ways of producing such a meter. Professors Greene and Moody, of Rensselaer Polytechnic Institute, have conducted a series of experiments there which resulted in the production of a meter practically giving only the resolved components of velocity.

A conclusion to be drawn from these experiences is that a tail, or rudder, is a useless appendage to a meter used in stream gauging. The meter should be held rigidly in the stream or conduit, giving only the component of velocity perpendicular to the cross-section. A cup meter would give better results in turbulent water if it had no tail, but was simply allowed to run at the end of a vertical rod like an inverted cup anemometer.

The recording device for a meter designed to be held rigidly n the current should register positively for down-stream cur- ent and negatively for up-stream current. There are cases here the current beneath the surface is up-stream; and the ld forms of meter make no distinction, as they should.

Accuracy of Velocity Determinations by Current Meters.— Under given conditions, the current meter is a very accurate nstrument. To prove this, it is only necessary to take a series f observations at a given meter point, or better, at a given et of meter points, when conditions at the gauging section are onstant. Repetitions of these observations will give results hecking within 1 per cent.

It is not even necessary to take observations under constant onditions, as is shown by the writer's plottings of the sums f the metered velocities at selected sets of meter points t various gauging stations. These curves are drawn through he plottings of points the co-ordinates of which are the ele- ation of the water surface at the given gauging station and he sum of the velocities at a selected number (25 to 100) of eter points in the cross-section. In shallow streams the eter points should be at mid-depth.

Even in the case of shallow, turbulent stony streams, such lotted points all lie within 1% of the finally determined curve, hus showing that the performance of the meter, be it of rew or cup type, is uniform and reliable.

The main sources of error are in the application of the still- ater rating, the determination of the section area, and the termination of the distribution of flow through the cross- ection. The errors due to an erroneous determination of the istribution of velocities are frequently styled the "errors due the method of calculation."

Distribution Factor.—If the discharge and section area are termined accurately for any one gauging, the mean velocity the section may be divided by the sum of the velocities at selected set of meter points. This ratio may be called the istribution factor for the corresponding stage of the water. this way, corresponding values of the distribution factor nd stage of the river may be determined and plotted, the co- rdinates being the elevation of the water surface and corre- ponding value of the distribution factor. If the work has en good, the points will plot as close to a smooth curve as e plotting of points representing the sums of velocities at e selected set of meter points.

Section Area.—The section area, next to the error in applying the still-water rating, is probably the most uncertain element of a discharge determination, where the stream is shallow and stony. Nevertheless, it has been ascertained that the surface profile of such streams at reasonably good stations is a function of the stage of the water, in many cases being simply a horizontal line. By taking a minutely accurate profile of the bottom of such a stream along the cross-section, and a number of surface profiles at various stages, the section area may be plotted to the corresponding elevation of water surface. This is another element for the accurate determination of a discharge curve.

Statistical Synthesis of a Discharge Curve by Means of its Generating Elements.—According to the definitions given above, there are three principal generating elements of a discharge curve, all of which may be exhibited as curves plotted to the elevation of the water surface at the cross-section. These generating elements are, respectively, the sum of the velocities at a selected set of meter points, the distribution factor, and the area of cross-section.

If, for any given stage of water, the corresponding values taken from the curve of sums of velocities and the curve of distribution factors be multiplied together, the result is the mean velocity in the section for that stage. The product of this mean velocity and the section area taken from the area curve for the same stage is the discharge for that stage. In this way the discharges of the stream may be computed for all stages and plotted as a finally determined discharge curve.

The method is as strictly statistical as though the laws of probability had been applied formally, and the result is practically as satisfactory and infinitely easier to obtain. Moreover, errors are immediately detected and located.

Good work on the mountain streams of North Carolina and Tennessee has shown that individual discharge determinations based on the foregoing processes will plot within 1 or 2%, as extreme errors, of the final discharge curve.

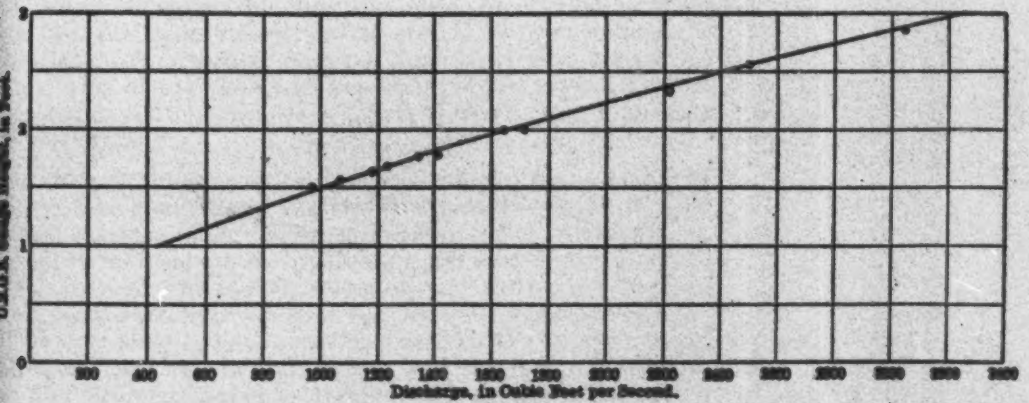
SMOAT ON
CUP AND SCREW CURRENT METERS.

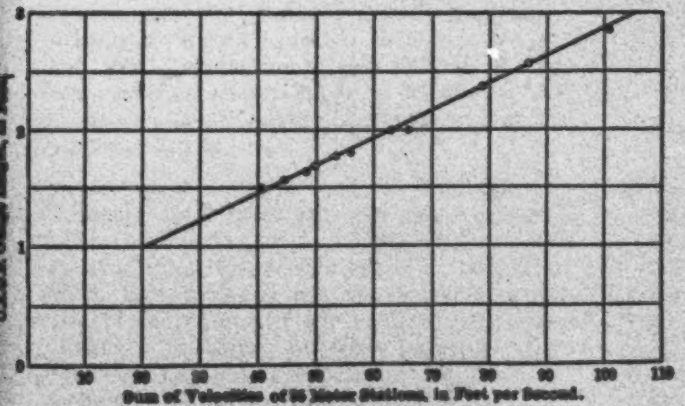


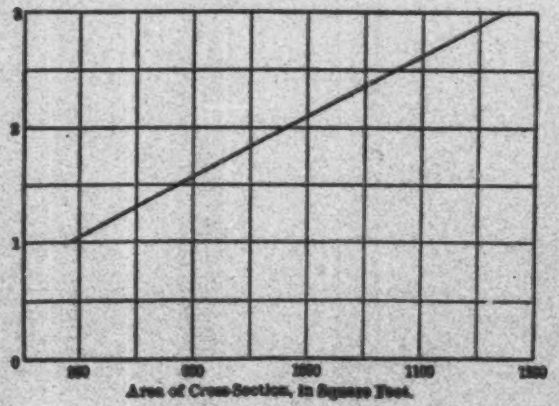
DISCHARGE CURVE FOR TUCKASEGEE RIVER AT BRYSON, N. C.

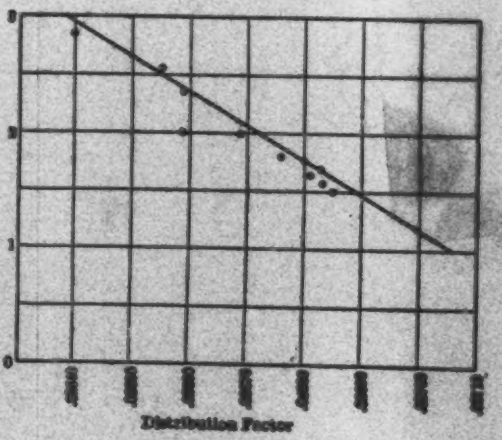
- Observations with Gurley Meter
- Observations with Haskell Meter

The discharge curve has been computed from the elementary curves obtained from observations with the Haskell Meter.

The points spotted on the discharge curve indicate the individual discharge obtained from each gauging.







Distribution of Flow.—The distribution of flow is determined in the ordinary manner by vertical velocity curves. It is best, however, to be systematic. A good system is to determine the ratio of the mid-depth velocity to the mean velocity in each vertical for the whole range of stages of the river. The writer has used an average value of these ratios for each stage of the river, by which the mean mid-depth velocity for the corresponding stage is to be divided, in order to obtain the mean velocity in the section before computing a discharge. In practice, a curve may be drawn giving the mean value of the ratio for each stage of the river. The determination of this ratio is a different thing from a gauging for discharge.

Discharge Gauging.—As described above, the writer prefers to take gaugings of shallow rivers at mid-depth at equidistant stations along the cross-sections. The individual discharge is then computed by dividing the sum of the products of the corrected mid-depth velocities and their corresponding areas by the average value of the before-mentioned ratio for the proper stage. The discharges at the ends of the section, below obstructions in the stream and around and through piers of bridges, should be treated separately under the title "end discharges" or "additional discharges." This additional discharge may be plotted as a function of the stage of the river. Such a plotting shows whether the calculation has been made on a consistent basis by forming a well-determined curve. Otherwise, the computer has varied his method of attack inconsistently.

Error in Using Average Ratios.—Undoubtedly, an error is made in using an average ratio of any sort, unless that average be determined properly. Thus a time average and a space average of a quantity are two entirely different things. It is important, therefore, to use the correct form of averages. However, if the values of the ratio of mid-depth velocity to mean velocity in thirty or forty verticals at a station of fairly uniform depth and velocity all lie between 1.10 and 1.18 as extremes, with an arithmetical average of about 1.14, no serious error can result in using such an average value. In fact, in this particular case, a detailed computation and one based on the average value of 1.14 differed by only one-seventh of 1 per cent.

Room for Research.—In the writer's opinion, it would pay scientific investigators to develop a meter which under all con-

ditions would give the resolved component of velocity in a given direction, rather than to attempt to determine any functional relation between the deviations of cup and screw meters from their still-water ratings. In the foregoing studies of the results at Massena it was thought sufficiently accurate to consider the error of the cup meter about six times the error, in the contrary sense, of the screw meter. This ratio is undoubtedly a variable, but no serious error can result by assuming it to be constant where the extremes observed would make less than 1% difference in the discharge, as was the case in the turbine tests at Massena.

Practical Application of the Methods.—Table 8 exhibits the results of a number of discharge determinations at a station where the turbulence of flow is at a minimum. In fact, the disparity between the records of the Haskell and Gurley meters is less in these observations than for those at any of the other stations operated in North Carolina and Tennessee. The average ratio of mid-depth velocity to mean velocity in the vertical, for 45 vertical velocity curves, is 1.055. The curve has not been drawn.

TABLE 8.—Results of a Number of Discharge Observations Taken at the Station at the Wagon Bridge, Bryson, N. C.

*The velocities are here based solely on the still-water ratings of the meters.

Plate XXVII shows the plottings of the main elements of the discharge observations of Table 8, according to the statistical methods described herein. The discharge curve is determined by the three elementary curves, as already explained. The elementary curves are plotted from the records of the Haskell meter.

DISCUSSION.

W. G. Price, M. Am. Soc. C. E. (by letter).—This paper gives the results obtained from a very large number of observations, and should be of much value. Before accepting these results as perfectly reliable, the writer would be pleased to know if the meters, in both the rating and stream tests, were suspended in precisely the same way and by supports of the same size?

Were weights used in both cases; and were they always the same distance from the wheel?

Was the skiff so far from the wheel that it did not push the water ahead of itself a trifle and thus reduce the rate of revolution of the wheel? In some cases, a steamer ascending the Upper Mississippi will check slightly the flow of the water some hundreds of feet ahead of itself.

The writer has had an extensive experience with current meters during a period of seventeen years, beginning with 1879, during which time he measured the flow in the Mississippi, Missouri, and Ohio Rivers, and their large and small tributaries, many times, and in many places. The following propositions are the result of his experience:

The thread of a perturbed current, of course, is longer than that of a steady current. A meter of the cup type, without a vane, measures the thread of the horizontal current perturbations, but when provided with a vane, it measures a trifle more than the thread of the horizontal perturbed current. This is due to the effect on the vane of the perturbed current which swings the wheel transversely to the current. If a cup meter with no vane is fixed on a vertical rod, the current perturbations moving up and down in the vertical plane will decrease the revolutions of the wheel and thus offset the increase due to the horizontal perturbations. This action is due to the fact that the top and bottom faces of the meter wheel present a propeller-shaped surface to the water, and when vertical currents strike the wheel they tend to turn it in the opposite direction from that produced by the water flowing against the cups. For this reason the vane should not be used in streams shallow enough to permit of it being omitted, if there are perturbed currents. Larger streams, when the gauging station is carefully selected, are not perturbed to such an extent as to cause a serious error in meter measurements.

A meter of the propeller type will measure less than the thread of the perturbed current, because of the inability of the

vane to keep the face of the wheel at all times precisely normal to the current. A current striking a propeller wheel sidewise does not increase its revolutions, as is the case with the cup meter. Each type of meter, in clear, straight, running water, will give the same accurate results, provided it has been accurately rated and is supported in the stream in precisely the same way as when rated, or by a method which does not produce an increase or decrease of current at the meter wheel.

When a weight is attached to the supporting rod under the meter, it reduces the discharge area and increases the velocity of the water in its vicinity, and thus increases the rate of revolution of the meter wheel. If the weight is placed 6 in. below the meter, the wheel, in each type, will run much faster than when the weight is 12 in. below the meter. A difference in the location of the weight, or the use of the weight in one case and not in the other, will produce all the difference, noted by the author for the Price meter, between ratings and stream measurements.

The propeller type of meter is often made to run more slowly between ratings and stream measurements by a slight quantity of grit blowing into the bearings, or being carried in by the water. This type of meter is often made to run slow by a particle of dead grass or leaf (found moving in most streams) catching on the propeller. The propeller type of meter does not free itself from such debris, as does the cup meter.

When meters are rated in still water, it is necessary to wait 10 min. or more after each passage of the meter for the water to become still again. If the wind is blowing against the surface of the water, variable and sometimes rotary currents will be produced, which will make the rating inaccurate. The surface currents will run in one direction and the under current in the opposite direction. For this reason, the meter should be rated at a depth of more than 2½ ft., and in water more than 5 ft. deep.

A rating taken in running water is likely to be the most accurate, because the running water carries away the disturbing currents produced by the movement of the meter.

When a cup meter is accurately rated in still water and in ordinarily steady running water, the two ratings will be the same within a small faction of 1%, and the rating curve can be drawn through all the plotted points obtained by the rating, so that no point will vary in revolutions as much as 1% from the curve.

The writer has used a Morse paper tape register and electric device to start and stop the register, or mark the paper tape, at the instant of passing the cross-wires suspended over the 200-ft. base, so that the fractions of revolutions of the cup meter wheel were determined at the beginning and end of the run; and such a rating in still water, with almost no wind, located all the plotted points within a very small fraction of 1% of the number of revolutions from the rating curve as drawn.

The ratings of both the Haskell and Price meters given on Plates XXIII and XXV are inaccurate, as the plotted points indicating the number of revolutions vary entirely too much. The errors in the Price ratings are apparently much greater than in the Haskell ratings.

Mr. Groat has conducted a series of observations in one tail-race where the currents were quite divergent, and the writer submits that the result of his experiment, treating as it does of one special condition, cannot be taken, either directly or by inference, to apply to general conditions of measurements of the flow of streams.

Under such peculiar conditions, where there are cross-currents, as in the Massena experiment, it is possible that the propeller type, owing to its peculiar construction, is less affected by such currents than the cup type; but if the propeller type were better for the measurement of streams where accurate measurements are impossible, owing to cross-currents, this fact would not indicate that such meters are better for general use.

A perfect still-water rating, of course, is what is required when the instrument is to be used in the measurement of straight, flowing streams. The usual rating in running water is made only to secure the same result as would be obtained by a perfect still-water rating. The small variations of the current from a straight line, as seen at the gauging section in most streams, makes only a negligible error in meter measurements.

A meter measures approximately the length of the curved thread of the current; therefore, if the thread is very divergent, inaccurate results will be obtained with any meter.

A gauging section having a perturbed current which would cause an error of 6% would give evidence to the eye by the boiling of the water, and would make the experienced observer hunt for a better section. However, better sections cannot possibly always be found.

A gauging section which has an up-stream current should never be used, and one which has very divergent currents can not give accurate results with any method of measurement.

The first meter used by the writer had a cup wheel which revolved in a horizontal plane. It was designed by Gen. Ellis, and had been used by him in the Connecticut River. This meter did good work in water which was absolutely free from grit. Floating organic matter, such as leaves and grass, did not often affect it, as the turning of the wheel caused such debris to free itself. When the attempt was made to use it in the muddy water of the rising Ohio in 1882, it gave very inaccurate results, owing to grit getting into the bearings, which made its rate variable. The writer was then furnished with two very finely constructed meters, designed by Clemens Herschel, M. Am. Soc. C. E., and made by Buff and Berger especially for this work. Each was of the propeller type, with horizontal shaft, having agate bearings, and each was provided with a vane to hold the meter in line with the current in both the vertical and horizontal planes. They were as perfect instruments of the propeller type as the writer has seen.

These meters were tested by rating them in clear water, and gave good results. They were then rated in a bayou of roily water, an overflow from the Ohio, and the results were very inaccurate, owing to grit getting into the bearings, and leaves and other debris catching on the wheel and continuing to revolve with it. They were tested in the turbid Ohio River with no better results.

It was absolutely necessary to have a meter which would do accurate work, if the great Ohio flood of 1882, which was then on its way, was to be accurately measured. In designing and constructing what is called the Price meter, on this occasion, the cup type of wheel was adopted, for three reasons: The friction of the bearings is so small that this wheel can measure sufficiently low velocities, which is not the case with the propeller type; the revolving wheel will clear itself of debris; and, by using a vertical shaft, with inverted cup bearings filled with air and oil which will stay in by capillary attraction, no water with its load of grit can enter. The friction of the bearings thus becomes a constant quantity. The well-known and successful operation of these meters is due to these three features, which the writer believes cannot be secured by any other design.

The propeller type of meter, designed by Mr. Herschel, was in service before the Price meter, but has had quite a limited use, while several thousand Price meters have gone into service. This test of time, under all kinds of conditions, indicates that the cup meter is the most efficient for general purposes.

The writer believes that with an accurately rated cup meter of the type having no vane—which is much the better design for shallow, perturbed streams—more accurate results could have been secured at Massena.

E. E. HASKELL, M. Am. Soc. C. E. (by letter).—The writer has been greatly interested in the results set forth in Mr. Groat's paper, for he has never had occasion to use current meters under just such conditions.

The current meter was designed originally to measure velocities in open channels. It has developed into two distinct types: those having screw wheels and those having cup wheels. The first current meter, "Woltman's Mill," more than 100 years old, was of the screw wheel type. This meter has undergone various changes in form and in the mounting of its wheel, and, on the whole, has proved to be very accurate and reliable. The origin of the cup wheel meter is not as definite. It has undergone various changes, and the cups have been of various forms, namely, cones, hemispheres, and combinations of cones and hemispheres. Although a great deal of good work has been done with meters of this type, they have not shown themselves to be anywhere near as reliable as those of the screw wheel type. In the writer's judgment, this is due to the fact that they do not always present the same area and form of wheel to the current pressure. The tilting of the meter, even through small angles, changes these, and consequently changes the rating curve or equation. In current meters of the screw wheel type, such tilting through small angles makes but a slight change in the area and form of wheel presented to the current pressure, and, accordingly, they follow much more closely their rating curve or equation.

In the last paragraph on page 836, the author states, as follows:

> "A conclusion to be drawn from these experiences is that a tail, or rudder, is a useless appendage to a meter used in stream gauging."

The writer's experience will not allow him to accept this conclusion. In a large river, the difficulty of holding the axis

of the meter perpendicular to the cross-section becomes so great that it is out of the question. In large streams it is necessary to measure both factors, velocity and direction, and reduce to obtain the velocity normal to the cross-section. In small streams or tail-races it is possible to hold the meter rigidly in place; but, when thus held, if the direction of the current makes an angle with the horizontal, that is, strikes the wheel of the cup meter either on the top or bottom of the cups, it will over-register as readily as if running in "eddies" or "boils." The amount of this over-registration depends on the angle which the direction of the current makes with the horizontal, and can only be determined by some check method.

It is not at all clear to the writer why a still-water rating of a current meter should not give an entirely satisfactory result. In all cases where the elements of the current in the open channel are reasonably parallel, the meter is working under almost the same conditions as when drawn through still water. In one case the meter is free and the water moving, and in the other the meter is free and moving, and the water still.

The following test of a direction current meter was made after it had been rated in still water. It was made in a large tidal channel, free from "eddies" or "boils," where the elements of the current were parallel. Each comparison was made by running the meter for 10 min., and in this time running ten large cylindrical can-floats, alternating on each side of the meter. The determined velocities are in feet per second, as follows:

Float	1.04	1.29	1.55	1.94	2.56	2.65	2.76	2.80	3.08
Meter	1.05	1.28	1.55	1.96	2.59	2.64	2.74	2.82	3.11

The greatest uncertainty in the results obtained with cup wheel meters is caused by using such meters from an unstable support, like a boat, particularly if the weather conditions are such as to give the boat any rocking or pitching motion.

The author is deserving of much credit for his work and his paper. Well planned and well executed work cannot help but make for engineering progress.

CHARLES H. MILLER, M. Am. Soc. C. E. (by letter).—Although the writer has made scarcely any current meter observations during the past twelve years, and hence has not kept up fully with the progress in such work, he is much pleased at the opportunity to read such a clear presentation

of a series of observations, evidently made with much painstaking care; and is gratified to note such a complete verification, stated, however, in a much clearer manner, of a positive difference between a cup meter and a screw meter when running in perturbed water; which difference the writer noted just a short time before leaving the Government service, and has never had opportunity to investigate further.

Although the difference was then cited as being due to instability of support, in other words, the rocking of the skiff, this rocking was done for the purpose, not only of causing conditions actually to be found in the river on account of "boils" and "eddies," but to show the effects that might be expected should the skiff or support be moved otherwise than in a straight and even course, while taking a rating in still water. That the writer was familiar with this source of error a number of years ago may be noted by referring to a letter* written by him, in which, in speaking about the rating of meters in skiffs, it is stated that "a rating should never be taken in a skiff which is being pulled with the oars," and that "the observers should be cautioned about keeping the same positions and not swinging their bodies from one side to the other while the observation is being made." This same passage was noted by the late William Starling, M. Am. Soc. C. E., and referred to in his paper entitled "The Discharge of the Mississippi River."†

Mr. Starling's paper treats in general of the many difficulties attending the taking of discharge observations on the Lower Mississippi River, and explains the reasons for some of the apparently discrepant results published in those days, he having had access, at the time, to the large mass of data gathered by the writer and others then engaged in wrestling with the problem of determining the extent of, or in eliminating, errors. It must be remembered that the possibility of error is very great when measuring the discharge of a river in which a favorable cross-section has a width of approximately ½ mile, with a maximum depth of 105 ft. at times, where velocities of 9 ft. per sec. or greater are found, and a total discharge of 1 750 000 cu. ft. per sec. may be obtained. Under such conditions, it is impossible to anchor the boat or equipment, and it must be held on one spot, as nearly as possible, by means of the rudder and the propelling power, counter-

Engineering News, January 24th, 1895, p. 58.

†*Transactions*, Am. Soc. C. E., Vol. XXXIV, p. 347.

balancing the current and wind forces. Careful observations were made to determine how much movement actually took place. In fact, a large portion of the time in the field was devoted to checking the accuracy of the observations. It may be noted that the meters then used were of the cup variety. Some checks, however, were made by a system of double floats.

As noting some of the improvements that were being made from time to time, attention is called to the fact that, at a time as recent as 1891, the meter rating was considered as following a straight line, and the proper straight-line equation was calculated by the method of least squares, often, however, not until some time after the field observations had been made. About the date just mentioned it became customary to plot the rating observations and draw the curve conforming as nearly as possible thereto, from which a rating table was taken directly. Other tables were made to cover all necessary computations in the discharge work, and each station observation was calculated while the boat or steamer was moving to the next station, so that the total discharge was known a few minutes after the last velocity observation had been made. For instance, during the morning of May 4th, 1892, at Arkansas City, Ark., the discharge was computed at 1 733 676 sec-ft. as compared with 1 532 875 sec-ft. for the day before. Another observation, made during the afternoon, gave 1 741 526 sec-ft., showing that some marked change had taken place during that time. On the following day it had dropped back to 1 589 172 sec-ft., or to about the general average at that time. Under the old methods, the observations were not computed until some time, often weeks, after the field observations had been made.

As illustrating the fact that every method that could be thought of at the time was used to eliminate errors, it will suffice to say that, in the case of a large and persistent difference in the discharge, as found at two stations 90 miles apart, new meters were purchased, later they were interchanged, frequent ratings were made, and finally the observers exchanged places with each other; all this was done without finding a satisfactory reason for the difference. This was in 1892. During the high water of 1893 these same stations were again occupied, and further efforts were put forth to get accurate results. Mr. Starling, in the paper previously cited, has this to say regarding this work:

"In 1893, the discharges at Arkansas City and Wilson's Point agree fairly well; and when checked by the results of the flanking observations, they present a very coherent mass of data, affording the most trustworthy measurement of the extreme high-water discharge ever obtained on the Mississippi."

Too much stress cannot be placed on the fact that it is just as important to avoid errors in rating meters as in taking the actual discharge observations; and the writer is strongly of the opinion, based on long experience in the field, that by far the larger part of the error is due to the fact that ratings are usually made under physical conditions which are widely variant from those under which the discharge observations are made. For instance, if the observations are to be made from a steamer, then the ratings should be made from the same or a similar steamer, and in dead water, if possible, although they can be made accurately in moving water, provided the movement is smooth, generally uniform, and slow enough to permit the taking of slow velocities in the downstream direction. Care must be exercised in keeping the meter below the influence of the "drag" occasioned by the steamer hull moving through the water.

Necessarily, the official reports, on account of limited space, as a rule, can contain but a brief explanation of methods and results; and, naturally, these reports incline toward the better showings, failing in general to recognize the fact that the publication of actual failures will often hasten the time of the final solution of the problem.

It may be of interest to know that the first forms of meters were of the wind-mill, screw, or propeller type; that is, the vanes turned, in a plane which was perpendicular to the direction of the current. These were used on South American rivers in 1871.

To eliminate the tail or rudder appears to be a move in the right direction, but a vertical rod could hardly be used with success in gauging a stream as large as the Mississippi, and it would no doubt be possible to work out a design which could be mounted concentrically on the cable which is now used to lower the meter, with its attendant lead weight, to depths of 60 ft. or more, affixing the tail or rudder to the lead weight, and placing the latter so far below the meter that it would not influence its running.

JOHN C. HOYT, M. Am. Soc. C. E.—Although more than fifty devices for measuring the velocity of water have been patented, the only meters which have had general use are the Price, Haskell, Fteley, and Ellis, or modifications of these.

Each of the various meters has first been devised to meet the requirement of some special condition, and may or may not be applicable to other conditions. Therefore, a current meter should never be used for other conditions than those for which it is designed or has been found to be applicable.

In 1888 the United States Geological Survey began gauging streams of all sizes and in all sections of the country. These streams presented an infinite variety of combinations of range in depth, width, and velocity, were often remote from railroad or other regular transportation facilities, and were consequently difficult and expensive to gauge. No adequate instruments or methods had been developed for work of this varied nature. Furthermore, elaborate equipment and methods were out of the question on account of the limited funds. It was necessary to devise or adapt a current meter which could be readily carried in the field and operated by one man, either from a bridge, boat, cable and car, or by wading.

To fulfill these requirements it was essential: (*a*) that the meter should be simple and light in construction, with no delicate parts which easily get out of order; (*b*) that it should be simple in operation, including its preparation for use under any conditions, and its dismantling, cleaning, and boxing after use; (*c*) that it should offer a small area of resistance to the action of the water; (*d*) that it should have a simple and effective device for indicating the number of revolutions of the wheel; and (*e*) that it should be adaptable for use under all conditions.

After experimenting with various types, the engineers of the Survey developed a meter combining certain essential features of the Price acoustic and the large Price electric meter. This is known as the small Price electric meter, and is now in general use in the Survey work. Modifications in its construction have been made from time to time, until now it represents the ideas of many engineers based on results of more than twenty years of experience in stream gauging.

The limitation of the Price meter pointed out in this paper, namely, that it may be effected by cross-currents, has always been recognized by its designers and users. Therefore, special care has been taken to restrict its use to work where the conditions are such that errors from this cause will not affect

the final estimates of discharge. These requisite conditions are: (*a*) a fairly smooth bed; (*b*) a measurable and steady velocity of current; and (*c*) a stationary stage during the measurement. The velocity of the current should vary gradually throughout the section, which should show no marked eddies, cross-currents, or boils, and its mean should not be less than 0.5 ft. per sec. at low stages. After visiting hundreds of gauging stations, on streams of varied character, in all sections of the United States, the speaker is convinced that only the exceptional station is not or cannot be located in accordance with these requirements. This statement is made in order to correct any impression which may be drawn from Mr. Groat's paper, that the Geological Survey records, based on measurements with the small Price meter, generally involve large errors. More than two hundred engineers have been engaged in the stream gauging work of the Survey for various periods during the last twenty years, and, as far as known, no valid criticism of the methods used has ever been made which was not fully appreciated by the Survey engineers; and they have made combined effort to correct, as far as possible, each defect in the work as soon as it is discovered. The instruments and methods have been subject to continual change, and old have been supplanted by new whenever the new have been proved the better. Constructive criticism of the work is, and has always been, welcomely received and acted upon, and this opportunity is taken to appeal to engineers who are interested in the use of stream flow records for more constructive criticism and for co-operation in raising this branch of hydraulics to the high plane for which all who are engaged in it are striving.

A few points in Mr. Groat's paper may be referred to briefly:

1.—The paper calls attention to the recognized fact that the differential meter is affected by cross-currents.

2.—It is believed by the speaker that the methods used in carrying on the work from which the conclusions in the paper were drawn, and the magnitude of the results obtained, are both open to question.

3.—Unfortunately, the methods are described only in a general way, and various factors which might affect the results materially are not adequately presented. Furthermore, sufficient data for making any exhaustive study of the results are not given. Therefore, any detailed discussion of the work is impossible.

4.—The large Price meter used in the work is of a type which has not been used for several years by engineers who are most familiar with stream gauging. In the work of the Geological Survey, it was abandoned several years ago, when fifty meters of this style, all practically new, were condemned and replaced by the small Price meter, which was found to give more satisfactory results.

5.—The reader is left in great doubt and uncertainty in regard to the standards used in the comparisons. Though the Haskell meter used may not be seriously affected by cross-currents, there are no experimental data, as far as known to the speaker, which show that this meter gives results any more accurate under the adverse conditions stated than does the Price meter.

6.—The results obtained with an unrated Pitot tube do not appear to be sufficiently conclusive for any final deductions. The Pitot tube itself has had no extended use in open channels, its behavior has not been fully investigated, and, in the limited experiments which have been made with it, many questions have come up which leave an uncertainty as to its action. It has been demonstrated that its rating does not hold near the sides of a canal, and it has also been shown that it will not measure the true velocity when the opening is not in line with the current.

7.—The paper points out a well-known defect in the Price meter, but gives no remedy, and offers no substitute which can be used under a wide variety of conditions.

8.—The assumption that the differences shown by the so-called still-water ratings of the meters apply when the meters were used in the canal is questionable. The amount of difference between the Price and Haskell meters, when rated under the conditions mentioned, will depend on the amount of disturbance introduced into the rating; as the Price meter will record, not only the horizontal motion, but also the vertical motion and the cross-currents.

9.—The experience of the Geological Survey shows that accurate ratings of the current meter cannot be made from boats, owing to the errors introduced in connection with obtaining the various factors entering into the rating. Changes in the methods of rating by the United States Geological Survey, the Bureau of Standards, and the Rensselaer Polytechnic Institute have changed the results of ratings about 3 per cent.

10.—The speaker is unable to see why one familiar with current-meter work would have attempted to use the Price

current-meter under the conditions found at Massena. Engineers of the Geological Survey have frequently refused to co-operate in work where similar conditions existed.

11.—The statistical synthesis method, as understood by the speaker, does not take into account the relative distribution of velocities and areas in various parts of the cross-section. The mean velocity in a cross-section, as defined by the Geological Survey, is obtained by dividing the discharge by the area, which will not give the same results as taking the mean of the velocities at various points in the cross-section. For example, a certain stream may have 50% of its flow in 10% of its cross-section. Furthermore, this method of computation has no apparent advantage over that ordinarily used, and has the disadvantage of being much more complicated, even if the results are of equal value.

12.—The question of the distribution of velocity in the vertical has been investigated most thoroughly by the engineers of the Geological Survey, who have found the mid-depth method to be the least desirable. The mean of the velocities at two-tenths and eight-tenths of the depth gives (without a coefficient) the velocity in the vertical, under all conditions of natural flow; and, next in value, the six-tenths depth method has been found to be the most satisfactory.

The only method yet devised for rating a current meter is by drawing it through still water. A close study indicates that no material error is introduced in the results obtained with this instrument on account of the method of rating. Large numbers of comparative measurements have been made with the Price current meter, calibrated weirs, and measuring tanks, all of which show that the meter, when properly used, will give results accurate within 1 or 2 per cent.

It has also been found that measurements at different points on a stream, where the conditions of measurement are entirely different, give results which agree closely. Many measurements have been made on two tributary streams and then on the main stream below, and the results check within the limits of accuracy necessary in work of this type.

C. W. Stanford, M. Am. Soc. C. E.—The speaker would like to ask Mr. Groat or Mr. Hoyt whether any of the current meters mentioned—the Haskell, the Price, the Ellis, or perhaps the admirable German instruments—after being rated in fresh water (still water, of course), have been used in salt water; and what percentage of accuracy can be obtained with such meters in salt water?

If such instruments have been rectified against corrosion, and against short-circuiting, can they be relied on when used in salt water?

B. F. Groat, Assoc. M. Am. Soc. C. E. (by letter).—If one will examine the papers and discussions concerning current meters published since the original study was made by Frederic P. Stearns, Past-President, Am. Soc. C. E., in 1879,* it will be found that there is much uncertainty among engineers concerning the reliability of these instruments, with which, up to the present time, there does not seem to have been any generally satisfactory and generally adopted practice. These facts are in sharp contrast to those connected with the use of other engineering instruments, such as the transit and level. No method can be deemed generally satisfactory until it meets the general approval of practitioners. So long as there is lack of agreement between various classes of current-meter observers, not only as to the general method of procedure, but also as to the reliability of various types of instruments, there can be no such thing as a satisfactory current-meter practice.

When it becomes generally realized that current meters obey their still-water ratings only when the conditions of flow are ideal, and that cup meters are affected in one sense and screw meters in the contrary sense, it will be apparent that there is a real reason for the diversity of opinion concerning the reliability of current-meter work.

The writer, therefore, was inspired by the hope that this paper might reopen the discussion and possibly put in motion an effort to improve the current meter.

Appended to the paper there is a brief description of a new system of taking discharge observations and a new method of constructing the discharge curve. This system and method have been applied most successfully in a number of cases, and are worthy of the attention of those contemplating a series of gaugings at one or more stations.

The method of synthesizing a discharge curve is not an invention of the writer which he is trying to introduce, but is a well-stablished method used by physicists and practicing engineers in determining various kinds of relations between observed magnitudes. It consists simply in separating a given investigation into its elementary parts and drawing a curve for each, the final relations being derived from the elementary curves or relations. The fact that the sum of the

*Transactions, Am. Soc. C. E., Vol. XII, 1883, p. 301.

velocities at a given set of meter points at a gauging station forms such an elementary relation, when plotted as a function of the gauge height, leads to the term "statistical."

The main advantage of the statistical method is that the entire series of gaugings, extending over a long series of years, may be connected into a consistent whole. The peculiar characteristics of a station may be studied from the elementary curves. If any change or break occurs in one or more of the elementary curves, a corresponding change or break has taken place in one or more of the physical characteristics or hidden conditions of the station. This is especially true of the sum of the velocities at a given set of meter points, because the sum forms a fixed relation between velocity and stage. The sum is chosen because, in taking a number of velocities, the accidental variations and errors in the velocities eliminate themselves. That is why, even at turbulent stations, a smooth curve can be drawn through the plotted values of the sum, with errors well within 1 or 2%, as extremes. It is not likely that changes in the hidden conditions at a station would be detected by any other method. They would be set down simply as unaccountable variations.

Another very important advantage of the statistical method is that it affords at once the most independent and most easily secured check on the velocity readings. Indeed, the sum of the velocities must plot on a definite curve, and this enables one to check the meter work at any newly observed stage with that at any other stage within 10 min. after all the velocities for the former have been recorded.

The writer is glad to know that his Conclusion 1, concerning cup meters, is generally recognized. Under certain nearly ideal conditions, such meters will give good results, but, the moment the conditions are changed in the slightest degree, the still-water rating becomes more or less inapplicable, with a resulting constant or systematic error.

Nevertheless, it would be perfectly safe to use a cup meter in turbulent water if, where used, it were rated with a Pitot tube. The fact that the meter runs with fidelity under such circumstances is another of the conclusions drawn in the paper, and one should not lose sight of this good quality. It may also be remarked that this is a fact which does not seem to have been generally recognized. Cup meters will undoubtedly have their uses, but improvements in the means for obtaining their ratings—not still-water ratings, but actual ratings at the time and place of use—are imperative. It will

do to talk about refined ratings when probable errors are reduced to values of less than from 3 to 5 per cent.

After reading the discussions one can scarcely shake off the idea that the niceties demanded for the conditions under which cup meters must be rated are altogether out of proportion to the degree of accuracy attainable with these meters in stream gauging. If a cup meter cannot be rated accurately from a boat when operated carefully, owing to changes in rating due to the slight irregularities of motion, what must be the effect on such a meter when subjected to the far greater irregularity of the motion of the water at a fairly good gauging station, to say nothing of the errors to be expected at a really turbulent station.

The writer believes that Mr. Miller made an important discovery in current-meter engineering when he noticed that cups over-register considerably and screws under-register slightly in agitated water. In due time this fact will impress itself on engineers generally, and lead to a meter which obeys its still-water rating more closely than any hitherto made.

The Haskell meter is so nearly correct under a wide range of conditions that it would seem to require only slight modification, as suggested in the paper, to render it almost independent of conditions. It would be a delightful task, for some one who has the time and means, to develop such a meter. Meantime, it cannot be too strongly urged on hydraulic engineers that a screw current meter is the most reliable kind for measuring the velocities of flowing water when using the still-water rating.

It may be well to define the terms "cup" and "screw," as the writer does not wish to apply the general propositions stated to every kind of instrument which may chance to be called a cup meter or a screw meter: A cup meter is one in which the rotating element operates on the principle of the Robinson cup anemometer, though the shape of the cups need not be limited to that of the hemisphere. A screw is a rotating element the surface of which would be generated by a straight line perpendicular to, rotating uniformly about, and moving uniformly along, the axis of rotation.

One would also hesitate to apply the propositions to meters having large or badly designed frames which would be likely to interfere with the action of the water on the runner. Although the frame of the cup meter is at the rear of the runner, it has decided and different effects on the rating of the

instrument when turned somewhat to the right and then an equal angle to the left of the line of motion.

The writer is more than pleased to have Mr. Price's open-minded discussion. The cup meter is very ingenious, and the means which Mr. Price has adopted to protect the bearings and secure uniformity of friction have probably been the cause of the continuance of this meter in the Government service.

Mr. Price may be assured that the meter was suspended in precisely the same manner during the turbine tests as in the ratings. This applies also to the stream tests. No weights were used in any case, and the meter wheel was about 7 ft. in advance of the stem of the rating boat. The reaction of the boat on the screw must have been slight indeed, as the ratings from a car at the Rensselaer Polytechnic Institute do not differ materially from those by the boat.

Fig. 1 shows the rating boat, and below it the rod used to support the meter. The hooks on this rod may be adjusted so that any desired series of depths may be secured. From the staging on which the observer stood a ⅝-in. rod extended across the tail-race at a fixed elevation. The meter was attached to one end of a ¾-in. rod, about 2 ft. long, the other end of which was screwed into the supporting rod. There were seven hooks on the supporting rod during the turbine tests, any one of which could be hooked over the ⅝-in. rod on the staging, thus immersing the meter to the corresponding depth. Six rope clips were attached to the ¾-in. rod at the verticals in which the meters were to be operated. The rope clips served as stops at which to hold the meter rod, when taking observations in the verticals.

Fig. 2 is a rough sketch of the Pitot tube and supporting rod. The Pitot tube (to the right) is a copy of "Tube *N*," as described in Mr. White's monograph, referred to in the paper. The supporting rod (to the left) was designed to be operated from the staging in the tail-race, in the same manner as the supporting rod for the meters. On Fig. 2 is shown one of the hoops to engage the ⅝-in. rod on the staging, and also the eyes on both the Pitot tube and meter supporting rods to which a guy wire was attached near their lower ends, thus holding the rods and preventing bending.

Mr. Price states that the meter of the propeller type does not free itself from such debris as dead grass and leaves. This is too broad a statement, for there is at least one meter of that type which does free itself, and that is the Haskell. This meter has been used by the writer many times in streams

carrying much dead grass, leaves, twigs, sand, and mud. On no occasion did it catch the slightest particle or give any evidence of being affected thereby.

This is due to the effective shape of the runner, which Dean Haskell has undoubtedly designed expressly for the purpose. The up-stream end of the wheel is brought down to moderately pointed or conical nose which sheds all debris carried by the water.

The question of friction in a current meter is very interesting. Throwing out the case of low velocities, the necessity seems to be, not so much for a small amount of friction as for constancy of amount. If the resisting torque is large but constant, a rating should be fixed just as exactly as in the case where the friction is small and constant. Notice, too, that there is a resisting torque caused by the hydraulic skin friction on a screw, which can be made as large as desired by lengthening the vanes along the axis. In this respect, the screw is just as much a differential meter as the cup meter.

The retarding skin friction has a much longer lever arm than the bearing friction, and has a much larger resisting torque, so that the bearing friction of a screw meter offers a resistance of secondary importance. Further, the resisting skin friction is a fixed function of the velocity, varying approximately as the square thereof. Hence it is clear that the principal portion of the resisting torque is fixed for each velocity and cannot be changed. It follows that, if the meter is kept in only fair condition, the rating is not affected seriously by moderate changes in bearing friction. The truth of this was tested in the experiments at Massena by taking part of a rating while the bearing was dirty and stiff, then completing the rating after the meter had been cleaned and oiled. Let the reader select from ratings *E* and *F* of the Haskell meter, Plate XXIII, the points taken before cleaning and oiling the meter. The Haskell meter is not sensitive to moderate changes of bearing friction.

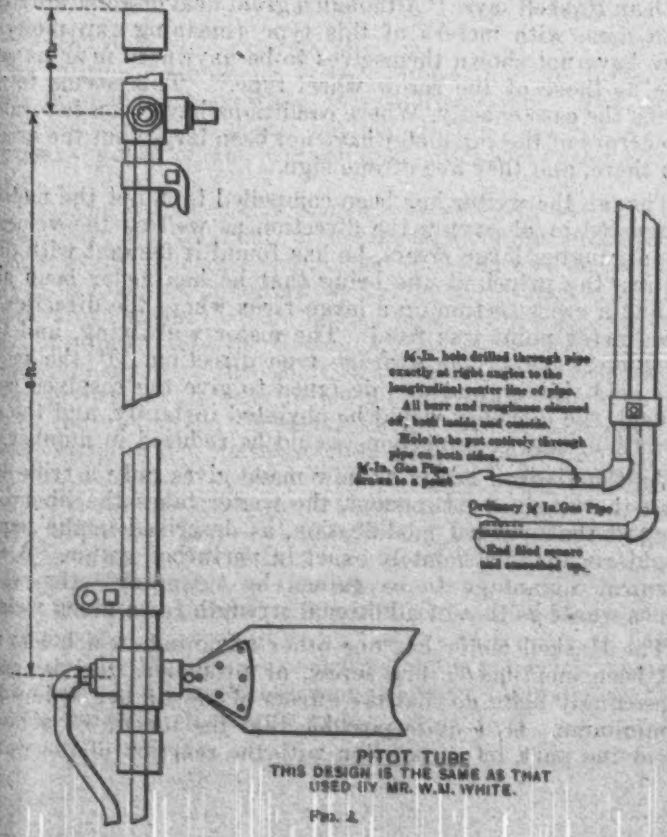
Mr. Price thinks the ratings (Plate XXIII) of the Haskell meter are inaccurate. If any one will take the pains to examine the percentage errors of the various ratings and the wide range of conditions under which these ratings were made, he will feel compelled to admit that the performance of this meter was very consistent throughout. Ratings of this kind are of more practical value than those obtained under restricted conditions, because the former afford an indication

of the degree of accuracy to be expected of the meter when in actual service, while the latter do not.

No doubt the rating line could be adjusted to the observations somewhat better. This rating line was located from a few of the earlier ratings, the later ones being plotted on the diagram subsequently. The change, if made, would be trifling, excepting for low velocities, which were not used.

The idea must not be entertained that the conditions in the Massena tail-races were bad. On the contrary, they were much better than those usually encountered in stream gauging. The flow of the water was parallel to the side-walls, and the meters might as well have been fixed rigidly to the rods, as far as concerned any tendency to swing. The errors of the meters were caused by small eddies and boils such as would certainly have to be dealt with at most gauging stations. The conditions of flow were carefully studied at each of the 84 meter points by using an inverted weather vane. An instrument was invented and used to ascertain the quantity of air in the water at each meter point. This quantity was found to be negligible.

Mr. Price states that a gauging station which has an upstream current should never be used, and one which has divergent currents cannot give accurate results with any method of measurement.



PITOT TUBE
THIS DESIGN IS THE SAME AS THAT USED BY MR. W.M. WHITE.

FIG. 2.

It may be that gauging stations with negative velocities should not be used, but do our current meters give any indication which would lead one to discard such a station when encountered? If the meter is 4 or 5 ft. under water, it cannot be seen; but it goes on recording the velocity just the same, even if the current is directed up stream, and the unsuspecting observer records a considerable positive velocity at the point, whereas it should have been recorded as negative.

As to the matter of divergent currents, the writer believes most fully that the problem may now be solved by using a screw meter held rigidly at right angles to the direction of flow. When the screw is modified, as suggested in the paper, it will increase still further the reliability of the results, even at the best of gauging sections.

Dean Haskell says: "Although a great deal of good work has been done with meters of this type (meaning cup meters), they have not shown themselves to be anywhere near as reliable as those of the screw wheel type." This seems to describe the case exactly. Where conditions have been favorable, the errors of the cup meter have not been large; but the errors are there, and they are of one sign.

Though the writer has been compelled to adopt the method suggested of observing the direction as well as the velocity, when gauging large rivers, he has found it fraught with difficulties, the principal one being that he has never been able to find a cross-section on a large river where the direction at each meter point was fixed. The meter will swing, and this completely masks the average true direction. If the meter was held rigidly, and was designed to give the resolved component, the difficulty would be obviated instantly, and the observations and computations would be reduced in number.

As the Haskell meter as now made gives only a trifle less than the resolved component, the writer takes the liberty to suggest that a slight modification, as described in the paper, might render it absolutely exact in perturbed water. A mechanical advantage to be gained by "cupping" the wheel vanes would be that of additional strength for a given weight.

The Haskell meter has one other advantage which has not yet been mentioned: The screw, or propeller, may be made exceedingly light, so that the effects of inertia are reduced to a minimum. It is quite possible that the inertia of a heavy revolving part, in conjunction with the reaction of the water,

may play an important role in changing the rating when the velocities become variable.

The still-water rating is not satisfactory at present because meters must be used in water which is more or less perturbed. Otherwise, the current meter becomes an instrument of limited use, and demands attention to a complicated system of details. As soon as a meter is produced which will resolve the momentary velocities at a meter point, the still-water rating will apply, even in perturbed water. Dean Haskell is to be congratulated on the fact that his meter almost does this very thing, so that probably only slight modification will be necessary to secure the desired result.

The float and meter comparisons are interesting. Applying the statistical method of summing the velocities in each case, the resulting comparison follows:

Sum of velocities by float	19.67
Sum of velocities by meter	19.74
Difference	0.07

Mr. Miller's discussion is very interesting, as it recounts work of unusual magnitude on the Mississippi. The writer has lived at various points on that river all his life, and remembers much of the Government work of various kinds there.

It is to be regretted that such a keen observer as Mr. Miller should have left the field of current-meter engineering. However, a useful fact once established is bound to live, and thus Mr. Miller its still potentially active in this branch of science.

Mr. Hoyt seems to fear that an impression may be drawn from the paper that the Geological Survey records, based on measurements with the small Price meter, generally involve large errors. This fear is hardly justifiable, as the writer states very definitely, "it seems certain that the correction for a cup meter when run at a good meter station on an open river is not large." On the other hand, it would certainly be on the side of safety to determine the degree of error in every important series of gaugings. One of the best ways to uncover an error of this kind is to run a cup meter and a screw meter in the section simultaneously. If the meters agree, there is no error. If they disagree materially, it will be found that the velocities by the cup meter are excessive, and those by the screw are deficient, the numerical value of such errors by the cup meter being relatively larger than those corresponding by the screw meter.

If any one wishes adminicular evidence as to the truth of this statement, beyond that afforded by the paper, he may refer to the paper, "Current Meter and Weir Discharge Measurements,"* by E. C. Murphy, M. Am. Soc. C. E. In this paper Mr. Murphy has, in the clearest manner, plotted the results of a number of comparisons of discharges by a weir with simultaneous discharges by cup and screw current meters.

In the case of the cup meters, practically all the discharges exceed the corresponding discharges by weir. This is indicated by the fact that practically all the points for the cup meters plot below the axis of abscissas in Fig. 2 of that paper.

In the case of the screw meter, the discharges are generally deficient, as the points generally plot above the axis of abscissas. Moreover, this is the more accurate meter, because the points average much closer to the axis, being in fact within 0.07% of it.

Mr. Hoyt concludes his discussion with several numbered paragraphs. They may be taken up in the same order:

1.—The paper does much more than call attention to the recognized fact that the cup meter is affected by cross-currents. It calls attention to the fact that the effect is productive of errors all on the side of excessive velocity, and that the screw meter is affected in the contrary sense, but to a relatively smaller extent. Though this was discovered by Mr. Miller years ago, it does not seem to have been recognized by anybody else since that time; but it is undoubtedly of the greatest importance to those who wish to improve the present methods of stream gauging.

Before carrying out any experiments at Massena, the writer was of the opinion that screw meters, like cup meters, would always show excessive discharges. This, he thought, would be the case because of the swinging of the meter and the consequent measurement of the thread of a sinuous, rather than of a straight, current. This, however, is incorrect. To prove it, attach a screw meter to the rating boat or rating car. Draw the meter over its course in the usual manner and count the revolutions. Then repeat the process, having all conditions the same as before, except that the meter is oscillated transversely to the direction of motion during its transit of the course. If the rating boat is used, the oscillation may be effected by rocking the boat. In the case of the car, some mechanical device may be used.

Transactions, Am. Soc. C. E., Vol. XLVII, p. 376.

Theoretically, the number of revolutions in the latter case should exceed those in the former case. Practically, the reverse is the case. The side-wash of the current has somewhat more than annulled the effect of increasing the length of the course.

2 and 3.—It is true that the methods used by the writer in making his discharge measurements were described only in a general way. Otherwise, the paper would have become so voluminous that the main facts would have been obscured. It must be remembered that the conclusions of the paper are not derived from a study of current meters *per se*, but are inductions from observations on the behavior of meters while testing turbines.

4.—The large Price meter was adopted as one type of meter to be used in the Massena tests, because the same type had been used by other engineers in the same tail-races several years before, and a comparison was desired. The results of the turbine tests would have been the same had the small Price, or any other cup meter been used instead of the large Price meter, because means were taken to correct the errors due to deviations from the still-water ratings.

5.—The standard adopted by the writer when comparing the cup and screw meters was the true velocity of the water. This appears when discussing Table 5, where it is shown that the cups over-register, on the average, by 5.6%, and the screw under-registers, on the average by 0.93 per cent.

When the Pitot tube and Haskell meter were compared, the Pitot tube was supposed to indicate, on the average, the true velocity. The result of this comparison was that the Haskell meter under-registered by about 0.6 per cent.

Thus there were two different methods of determining the discharge: (*a*) by cup and screw meters corrected through the medium of the boat-rocking tests, and (*b*) by Pitot tube and screw meter comparisons by which corrections were determined to be applied to the metered discharges.

It is worthy of note that these two methods of correcting the discharge, when applied to any given turbine test, give rise to a discrepancy of scarcely 0.3 of 1 per cent.

It is not claimed that rocking the boat is the best means for ascertaining the relative of errors of cup and screw meters. It is claimed that the nature of the case is such that extreme accuracy in this respect is not necessary. This is because the errors to be determined are not relatively large.

If it is feared that this paper is too daring in its conclusions to be credible, it may be well to search for independent verficiation. Such material may be found in Mr. Murphy's extremely valuable paper, "Current Meter and Weir Discharge Measurements," previously quoted.

Though Mr. Murphy gives an interpretation of the results of his experiments, yet he expressly states that he has "avoided in this paper a detailed comparison of results by different meters." Hence it will be permissible to analyze the results for the purpose of such a comparison.

The best method of eliminating accidental errors in comparing such a series of observations is the "statistical" method. In the case at hand, this method is particularly facile because comparable results may be obtained by the simple operation of summation.

In order the better to understand the conditions under which the tests by Mr. Murphy were conducted, it may be stated that they were made in the canal of the Hydraulic Laboratory at Cornell University. The discharge in each test was measured by weir and by two current meters. The two current meters were observed simultaneously in the same discharge section, one starting on the south side and progressing north while the other started on the north side progressing south.

There were twenty-five experiments, each made in the manner described. Ten of these were comparisons between the weir, Haskell meter No. 3, and small Price meter No. 363. Nine were comparisons between the weir, small Price meter No. 351, and small Price meter No. 363. Six were comparisons between the weir, Haskell meter No. 3, and small Price meter No. 351. Moreover, from these experiments may be selected sixteen in which the Haskell meter is compared with the weir, fifteen for Meter No. 351, and nineteen for Meter No. 363.

There are, therefore, six sets of experiments which may be compared statistically. In each case the aggregate discharge by the weir may be compared with the corresponding aggregate, or aggregates, by the meter, or meters, as the case may be. Table 9 gives the comparisons in tabular form.

TABLE 9.—STATISTICAL SUMMARY OF TWENTY-FIVE EXPERIMENTS BY E. C. MURPHY, M. AM. SOC. C. E., IN WHICH THE DISCHARGE OF A CANAL IS MEASURED SIMULTANEOUSLY BY A WEIR AND TWO CURRENT METERS, THE LATTER OPERATED IN THE SAME DISCHARGE SECTION.

Compiled from Table 1, *Transactions, Am. Soc. C. E.*, Vol. XLVII, p. 373.

No. of experiments.	Sum of all the discharges in all experiments, as shown by weir, in cubic feet per second.	SUMS OF THE DISCHARGES IN ALL THE EXPERIMENTS, AS SHOWN BY THE VARIOUS METERS.								
		Screw Type.			Cup Type.					
		Haskell Meter.			Price Meter No. 351.			Price Meter No. 363.		
		Sum, in cubic feet per second.	Error, in cubic feet per second.	Error, Percentage.	Sum, in cubic feet per second.	Error, in cubic feet per second.	Error, Percentage.	Sum, in cubic feet per second.	Error, in cubic feet per second.	Error, Percentage.
10	3 474.78	3 473.99	— 0.79	— 0.02	.....	.....	....	.....	.....	....

10	2 143.64	2 147.39	+ 3.75	+ 0.18	.....	.....	....	2 164.98	+ 20.55	+ 0.96
6	1 351.14	1 396.60	— 4.54	— 0.34	1 368.86	+ 37.19	+ 2.79	.....	.....	....
9	2 064.58	.....	....	....	2 070.77	+ 25.84	+ 1.39	2 094.01	+ 31.43	+ 1.54

The function of such a summary of aggregates is to eliminate in large measure the unavoidable accidental errors arising during the observations. Thus the remaining errors are each composed of two parts, namely, a large part, which is the net average constant error of the observations, and a small part, which is the net residual of the unequated accidental errors. From the approximate uniformity of the errors of the table, it may be concluded that accidental errors have been practically eliminated, and the computed errors for the sets of observations of greatest weight (the first three sets in the table) are the constant errors due to the meters, or due to deviations from their still-water ratings. Thus the constant error of the Haskel meter is —0.02%, that of the small Price No. 351 is +1.94% and that of the small Price No. 363 is +1.24 per cent. It may be inferred from the plottings by Mr. Murphy, on page 376 of his paper, that the average constant error of No. 351 should exceed that of No. 363. The reason for this is that the discharge by either of the meters

shows an increasing excess over the discharge by the weir with decreasing velocities, and there are relatively more observations of low velocity by Meter No. 351 than by No. 363. Had the reverse been the case, it might have been expected that the constant error of No. 363 would exceed that of No. 351.

It will be seen that the error of the Haskell meter for the ten comparisons with weir and small Price meter No. 363, is +0.18 per cent. This error, though insignificant, would have been negative had it not been for three experiments, Nos. 1-2, 3-4, and 5-6, in which this meter, for some unaccountable reason, gave discharges 4 or 5% greater than the weir. These three observations are plainly discordant, as may be seen by referring to the plottings for the Haskell meter in Fig. 2 of Mr. Murphy's paper. Had the meter run in these three experiments according to the same law as in all the other experiments, the errors for these three experiments would have been about nil. Thus the excess in discharge by the Haskell meter in the three experiments in question is about 25 cu. ft. per sec., as may be seen by consulting Table No. 1 of Mr. Murphy's paper. The aggregate for the weir from the writer's comparison, Table 9, is 3 474.78, and that for the meter would become 3 473.99—25.0=3 448.99. Thus the deficiency in the aggregate for the Haskell meter would be 3 474.78—3 448.99= 25.79. In other words, it is more than probable that the discharges by the Haskell meter are deficient by the slight percentage of 25.8÷3 475=0.75. However, it will not do to correct or reject observations simply because they are discordant.

It follows from the results shown in Table 9 that the cup meters in all cases gave excessive discharges and the Haskell meter gave relatively much smaller errors, the discharges being slightly deficient on the average. Therefore, the following general conclusions may be drawn from the results contained in Mr. Murphy's valuable paper:

(*a*) When a cup meter is run in moderately perturbed* water, it will register a larger number of revolutions per second than a perfect still-water rating would indicate.

(*b*) When a screw meter is run in moderately perturbed water, it will register a smaller number of revolutions per second than a perfect still-water rating would indicate.

*At the bottom of page 374 of Mr. Murphy's paper it is stated that there was a slight agitation of the water during the experiments.

(*c*) In the foregoing sense, a cup meter is affected relatively to a much greater extent than a screw meter.

(*d*) Either type of meter, when run in moderately perturbed water, will give uniform records in equal times, provided these times are sufficiently long, the flow of the water itself being subject to an established regimen.

(*e*) If both types of meter are used simultaneously in moderately perturbed water, the disparity between the discrepant velocities thus determined by the still-water rating may be taken as a basis for correcting the discrepant velocities.

(*f*) If the discharge by the weir be considered correct, the average error of the Haskell meter in Mr. Murphy's experiments was 0.02% on the side of deficiency, with a probability of its being slightly larger, and the average error of the cup meters was in the neighborhood of 1% on the side of excessive discharge.

(*g*) It would seem to follow that current-meter observations based on still-water ratings, without further correction, should be made with great caution. On the other hand, it seems certain that the correction for a cup meter when run at a good meter station on an open river is not large, and the corresponding correction for a screw meter may be negligible.

6.—It cannot be said that the Pitot tube used at Massena was an unrated instrument. It is an exact copy of one which was investigated as "Tube *N*" by Mr. White in the paper already referred to. It has a coefficient equal to unity.

In speaking of the accuracy of Pitot tubes, two distinct reactions must be kept in mind. One is the impulse of the moving water on the dynamic orifice, the other is the reaction of the static pressure and the moving water on the static orifice. If the static orifice is properly designed, the motion of the water, or the dynamic reaction, will have no effect on it; but the motion of the water will exert either suction or a positive pressure on an improperly designed static opening. It is this latter difficulty which has caused most of the uncertainty as to Pitot tubes.

Mr. White's experiments showed, in the most convincing manner, that the coefficients of all dynamic orifices of circular section, be they cylindrical, diverging, or converging, are exactly equal to unity. This was accomplished by towing a boat through the water with a number of different types of circular dynamic orifices attached somewhat in advance of the stem. The water stood at exactly the same level in all the risers, and the total head raised was equal to the sum of the velocity head and static head in each case.

7.—Although the paper does not essay to offer at once a complete remedy for the erratic behavior of current meters in perturbed water, it does point out the interesting fact that a close estimate of the true velocity may be made by using a screw meter of good design. If still greater accuracy is desired, both cup and screw meters may be used, the records being corrected by the observed relative deviations produced in some such manner as the rocking tests described briefly in the paper; or, even better still, the screw meter may be rated by a properly constructed and properly manipulated Pitot tube, under the exact conditions and at the exact point, or points, where the meter is to be used.

8.—The writer has oscillated a number of meters of different types, both longitudinally (up and down stream) and transversely (athwart stream and vertically). In all cases the cups were affected by increments several times as large as the decrements of the screws. This was for violent, as well as moderate, vibrations. It is true that the ratio is variable, values ranging from 3 to 6 having been noted; but, when the error between the cup and screw is not more than 7%, the application of the extreme ratios leads to corrections for the screw meter of only 1¼ and 1 per cent. Thus, an error of 100% in the true value of the ratio makes a difference in the final discharge of only ¼% for the case cited.

This method, of course, is only a practical way of getting an approximate result, but the approximation is shown to be close.

9.—A current meter which cannot be rated with sufficient accuracy from a boat will show even greater discrepancies when run at the average gauging station. The United States Lake Survey has done a great work on the Niagara and St. Lawrence Rivers, and its ratings were frequently made from a boat. The writer knows that screw meters were used extensively on this important work, but does not know whether

cup meters were also used. If the boat ratings had been unsatisfactory, it is certain that that fact would have led to a condemnation of such ratings. Possibly, if cup meters had been used, the boat ratings would have proven unsatisfactory. Of course, a rating made under laboratory conditions will plot almost exactly on a smooth curve; but a rating of a screw meter of good design will be nearly as good, if made from a boat.

It is presumed by the writer that the changes in the method of rating referred to by Mr. Hoyt were such as might be made by placing the weight too close to the wheel, or by running it near the sides, or bottom, of the tank. These are abnormal ratings, of a character which does not affect the question at hand.

10.—It has already been explained that the large Price meter was selected for the tests at Massena for the sake of comparison with the results of a former test in the same tailraces with a meter of this particular type. The writer is of the opinion that the results would have been substantially the same, even if the small Price meter had been substituted for the larger pattern. It must be emphasized that the conditions of discharge for much the greater portion of the gauging section at Massena were as good as those most frequently encountered at a good gauging station. The reliability of these tests cannot be questioned on this account.

The cup meter ran with great fidelity at any given point in the race. Its rating there, relatively to that of the Haskell meter or Pitot tube, was perfectly definite, a fact which does not seem to have been known heretofore. The trouble was not with the cup meter, but with the application of the still-water rating to the case. A raceway of uniform section can certainly be gauged within 1% of the true discharge. This statement is made because any given condition of discharge can be exactly reproduced at the observer's pleasure. This is one of the facts demonstrated at Massena.

11.—The distribution factor used in the statistical method is essentially a form factor. Its value depends on the shape of the solid constructed out of the components of velocity which are normal to the cross-section when these components are erected at their points of application. To every shape a particular value of the distribution factor attaches, but it is not true, conversely, that to every value of the distribution

factor a particular shape must attach. It is only necessary that shapes be equivalent as to discharge in order that two or more shapes may have the same value for their distribution factors. Hence it is not at all improbable that such changes of distribution actually take place at gauging sections without changing the discharge curve or rating table.

The mean velocity in the cross-section is the quotient obtained by dividing the total discharge by the area of the cross-section. The statistical method relies on this definition. In the turbine tests at Massena, the value of the distribution factor was ascertained by drawing the familiar contours of equal velocity over the cross-section of the race. The volume under these contours was computed, and, when expressed in proper units, was numerically equal to the discharge. This discharge was then divided by the area in order to ascertain the mean velocity.

By definition, the distribution factor is the ratio of the above determined mean velocity to the sum of the velocities recorded at the 42 meter points in the race. By actually computing this ratio, in the foregoing manner, for several of the turbine tests where the conditions were substantially the same, it was found that the value of the ratio—that is, of the distribution factor—was constant for given conditions. Consequently, it follows that the mean velocity in the tail-race may be ascertained simply by multiplying the sum of the observed velocities by the proper value of the distribution factor.

Though a somewhat different procedure was adopted in the Southern work, it was clearly proven that the distribution factor is a definite function of the gauge height, or stage of the river, which, when once reduced to a curve, may thereafter be used as the quickest possible means of ascertaining the mean velocity in the gauging section. This is accomplished simply by multiplying the sum of the velocities at a given set of meter points by the corresponding value of the distribution factor, as read from its locus.

In short, it has been demonstrated by these experiments that, in current-meter work, and discharge gauging in general, one may deal with aggregates of velocity area, and discharge, instead of individual values, with a gain in accuracy, time, labor, and satisfaction, to be realized in no other way.

Take, for example, the case of an observer who has just hurried to a gauging station to measure a discharge at a particular stage of the stream. He drops his meter at two or three dozen permanently established meter points (supposing the river is, say, 250 ft. wide), adds up all his velocities, compares the sum with his statistical velocity curve, finds the sum correct, and then multiplies it by a factor taken from a curve, the product being the discharge. The whole work may be done within an hour or two. Moreover, the observer knows his work is correct, because his velocity observations are checked.

12.—It is very certain that the Geological Survey has done excellent work in studying velocity curves and in formulating therefrom a few simple laws which govern the discharge of rivers. Much of this work is due to Mr. Hoyt with whose name is linked some of the most valuable hydraulic investigations.

For the most part, the writer's studies have been connected with shallow turbulent rivers, as he is frequently compelled to examine streams of this class with regard to the character of their flow. It may be of interest to know that he has arrived at two conclusions connected therewith. They are:

(*a*) A shallow turbulent stream may be gauged satisfactorily with a screw meter, or, better still, with a cup and a screw meter simultaneously.

(*b*) The proper point in a shallow turbulent section at which to take the meter readings is at mid-depth, otherwise the meter is too near the surface or too near the bottom to admit of accuracy.

Like Mr. Hoyt, the writer has summed up the measured discharges of two or more tributaries to find a good check on the discharge of the main stream. This does not prove, however, as a necessary conclusion, that the work at any of the stations is correct, as all may be, and sometimes are, affected by the same constant error.

In reply to Mr. Staniford: The writer has had only a limited experience with the current meter in salt water, in the form of a ship's log. This instrument was of the screw type, the runner being very similar to that of the Haskell meter. With care, such an instrument will give distances, and, there-

fore, velocities, well within 2%, even when the sea is agitated, assuming, of course, that there is no current or surface drift.

The Haskell meter was designed by Dean Haskell when he was working in salt water, and is adapted for use in both salt and fresh water. These meters have been used in coast harbors by officers of the U. S. Engineer Corps, and the Coast and Geodetic Survey; these officers would undoubtedly be able to state how fresh- and salt-water ratings compare.

ADAMS' EXHIBIT 7.
(Public—No. 92.)

An act to facilitate the collection of commercial statistics required by section 2 of the river and harbor appropriation acts of eighteen hundred and sixty-six and eighteen hundred and sixty-seven.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That owners, agents, masters and clerks of vessels arriving and departing from localities where works of river and harbor improvements are carried on shall furnish, on application of the persons in local charge of the works, a comprehensive statement of vessels, passengers, freight and tonnage.

Sec. 2. That every person or persons offending against the provisions of this act shall, for each and every offense, be liable to a fine of one hundred dollars, or imprisonment not exceeding two months, to be enforced in any district court in the United States within whose territorial jurisdiction such offense may have been committed.

Approved February 21st, 1891.

Loss that would be sustained by the City of Chicago and dependent populations were the present facilities for obtaining an adequate supply of pure water impaired or destroyed, based upon a comparative study of health statistics of the city for 13 years before and 13 years after the opening of the Chicago Drainage Canal.

Per Annum.

Per 100,000 of the Population.

Kinds of Loss.	From Increase in Typhoid Fever	From Increase in Other Diseases
I. By Loss of Contributions to Maintenance:		
a. Through premature death of male workers, 83% of 28.39x36x300	$254,488	$636,220
b. Through sickness, 83% of (483x10) + (28.39x2) + 52x300	23,400	23,400
II. By Decrease in Capital Building:		
a. Through premature death, 42.7x 36x40	28,256	70,640
b. Through sickness (726x10) + 52x40	5,581	5,581
III. By Unnecessary Dissipation of Resources: 483x58.41	42,405	42,405
	$354,130	$778,246

$354,130x23 = $8,144,900.

$778,246x23 = $17,899,658, which is the annual loss to the City of Chicago.

UNITED STATES LAKE SURVEY.

Ogdensburg, N. Y., Sept. 15, 1913.

From W. S. Richmond, Junior Engineer.

To District Engineer Officer, U. S. Lake Survey, Old Custom House, Detroit, Mich.

Subject: Preliminary Report, Hydraulics of Niagara River, 1913.

1. In accordance with your instructions, contained in letters dated June 13th and 30th, July 5th, August 12th and 22nd and September 3rd, hydraulic measurements of the Niagara River were made between July 5th and September 4th, inclusive.

2. Measurements of the volume of flow were made at two sections, one on each side of Grand Island, each section being about 4¼ miles below the foot of Squaw Island. Although, from the standpoint of configuration of the channel, slightly better sections might have been obtained further down stream, the adopted sections were selected because of the facilities they offered for range systems, and because of their nearness to a proper base of supplies.

3. The section in the west channel was called Oakfield, that in east channel, Wickwire. The field sheets of the upper Niagara River show the channels to be sufficiently smooth for some distance above and below the sections. There was no boiling or eddying of the water past or near the sections, and the average velocity was less than three feet per second. An inspection of the profiles and transverse and vertical curves, shows that good conditions for gaging obtained.

4. Practically the same equipment was used as on the St. Clair River in 1910, and on the St. Lawrence River in 1911. The personnel of the party was likewise much the same. Almost all the observing was done by the writer, or by Junior Engineer Albert B. Jones, who has been his ranking assistant for the past three years. In general, the same methods were used and standards of accuracy observed as in preceding years and set forth in various reports by the writer and others. Practically nothing in the line of field or office work was left unchecked. It was not expected, however, that the few measurements of current velocity which could be made in the brief time allotted to this work, would give final results quite as accurate as could be obtained from a much longer series of observations.

5. To one familiar with such work the procedure followed in field work and computations will, for the most part, be evident upon inspection of the field notes and the computations and sketches submitted.

6. At each section the horizontal distances depend on a base line measured with a good 100 foot steel tape, the length of base line being checked from the triangulation of 1909 of the International Waterways Commission.

7. The setting of the cut-off ranges was carefully checked.

RICHMOND'S EXHIBIT No. 1.
Feb. 4, 1914.

8. The rod floats were of rough hemlock, 2 inches square and 14 feet long, weighted at the bottom with scraps of lead to make them float vertically, with the tops projecting about 4 inches out of water. A piece of lath, about a foot long, extended 8 inches higher, and carried a flag 5 inches square.

9. The Buffalo gage was carefully and thoroughly inspected on July 9th and 29th, duplicate wye levels being run between P. B. M. Buffalo lighthouse, and the reference gages on the former date. The gage was also inspected August 18th and September 4th.

10. Small-type self-registering gages were established and maintained at Austin Street, Buffalo, and Chippewa, Ontario, in the exact locations of former gages. Unfortunately, the dock at Chippewa burned August 7th, destroying the gage, but the record was later rescued from the water, practically uninjured.

11. At the sections box gages were installed. Distances were measured with a wooden staff from a point on the top of the box down to the water inside.

12. Levels in duplicate were run to the reference points of all gages, from neighboring benchmarks, when the gages were installed, and when they were removed. All staffs were carefully tested.

13. Soundings were made exactly on section with a 140 pound cast iron weight suspended by number 30 steel piano wire. Locations were by cut-off angles read with a transit on shore, and were computed to the nearest foot.

14. Four Haskell current meters were used on their 40 pound weights. During current measurements for discharge or coefficient determination, two meters at a time were suspended 4 feet apart in the central forward part of the catamaran, 4 feet forward of the line joining the points at which the pontoon bows cut the water. The steering wheel, which was 15 feet astern of the port meter, was held on station.

15. Meters were rated two at a time, suspended from a cross-boom, so that each meter was 3½ feet from the side of the rating boat and 6 feet under water. The working draft of the rating boat was one foot.

16. No observations of current velocity were made when a passing vessel was on or near the section. During still-water ratings runs were seldom made when a boat was passing the mouth of the slip at the foot of Hertel Avenue, where the ratings were made, or for several minutes thereafter.

17. The results of rating number 2 are a valuable check on those of rating number 1, but were not used because they differed so very slightly from the first rating. The use of rating 1 for the discharge measurements is logical, and it is perfectly proper for the coefficient observations, where the meters were so used as to tend to eliminate errors of rating.

18. In gaging the flow through the areas at the ends of each section observations were taken while wading, or from the yawl, distances being obtained with tapes and tag-lines, depths with a sounding pole, and velocities with a small Price meter.

19. Water surface elevations at the various gages during discharge measurements were scaled directly from the records, allowing time intervals of −20, −10 and +60 minutes for the Buffalo, Austin St. and Chippewa gages, respectively. These time intervals were estimated from a consideration of carefully determined time intervals on the St. Clair River.

20. A brief summary of the results is as follows:

SECTION WICKWIRE.

No.	Date 1913	Inclusive Time	Water Surface Elev.			Wind	Meters	Disch.
			Buff.	Austin	Chip.			
1	July 30	9:12–11:35	573.35	568.01	563.08	NW 2	1B & 10B	95,200
2	" 30	13:30–16:23	573.01	567.82	563.01	NE 10	10B & 14B	92,800

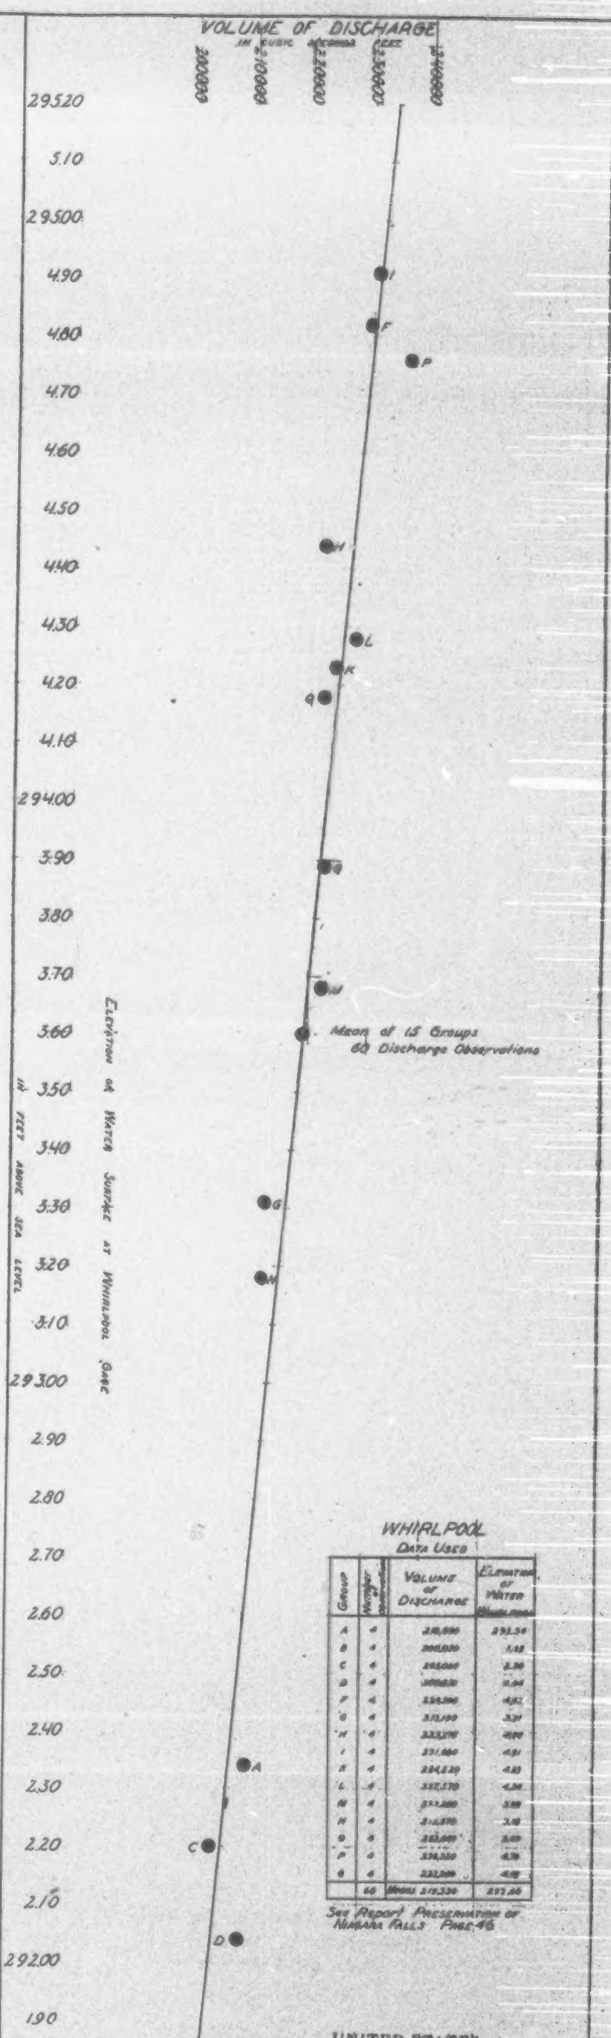
UNITED STATES
vs.
SANITARY DISTRICT OF CHICAGO

THE VOLUME OF DISCHARGE OF THE NIAGARA RIVER
PLOTTED WITH RESPECT TO THE ELEVATION OF THE WATER SURFACE AT THE
SUSPENSION BRIDGE GAGE

Equation of Discharge: $Q = 201060 + 9547(H_s - 340.00)$
Increment at Suspension Bridge is 9547
Derived Increment for Lake Erie is $9547 \times 229 = 21860$



WHIRLPOOL
Data Used

Group	Number Observations	Volume of Discharge	Elevation of Water Surface
A	4	218,690	293.34
B	4	209,030	1.88
C	4	203,000	2.36

	118	Mean 1.83	219,060

See Report, "PRESERVATION OF NIAGARA FALLS," Page 46, also Page 31.

Note: Group No. 1 contains the ten observations showing the highest elevation of the Suspension Bridge Gage.
Group No. 2 is made up of the ten next lower observations.
Group No 12 contains the eight observations with lowest gage reading.
Others are intermediate in order of gage height.

Mean of 12 groups
118 discharge observations

UNITED STATES
SANITARY DISTRICT OF CHICAGO
THE VOLUME OF DISCHARGE
OF THE NIAGARA RIVER
PLOTTED WITH RESPECT TO
THE ELEVATION OF THE
WATER SURFACE
AT THE
SUSPENSION BRIDGE
GAGE

Equation of Discharge $Q = 201,560 + 3445(H_s - 340.00)$
Increment at Suspension Bridge is 3445
Derived Increment for Lake Erie is $3445 \times 2.33 = 22,000$
The multiplier 2.33 is the ratio of fluctuation of the Suspension Bridge compared with Lake Erie at Cleveland, Ohio. See Exhibit H, Shenehon, April 15, 1914.
Lowerings of Lake Erie indicated by Derived Increment are as follows:
For Diversion of Chicago of 10,000 cu sec ft 5 3/16 inches
4,000 " " " 2 1/16 "
14,000 " " " 7 1/16 "
These conclusions are entirely independent of the Buffalo Gage readings during the observations for Volume of Discharge.

M. E. Shaffner, Del. Dec. 1913.

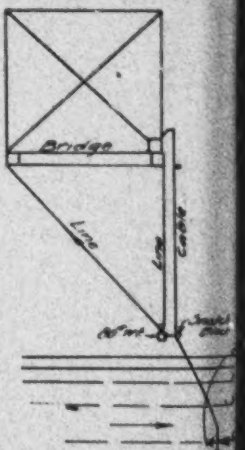
Water Surface 567.2 0.00

Weighted mean velocity in discharge 3.46 6.00

To obtain velocity in units corresponding to Percentages multiply h by 6.00



Meter was allowed to go downstream without guys at 1/4, 6 and 9/10 depths. At each depths was made to descend in a vertical line (in both planes) through its position at 8/10 Cable & sinker was used, no sinker with Cable assumed straight line below Snatch block.

WILLIAMS EX. 40.

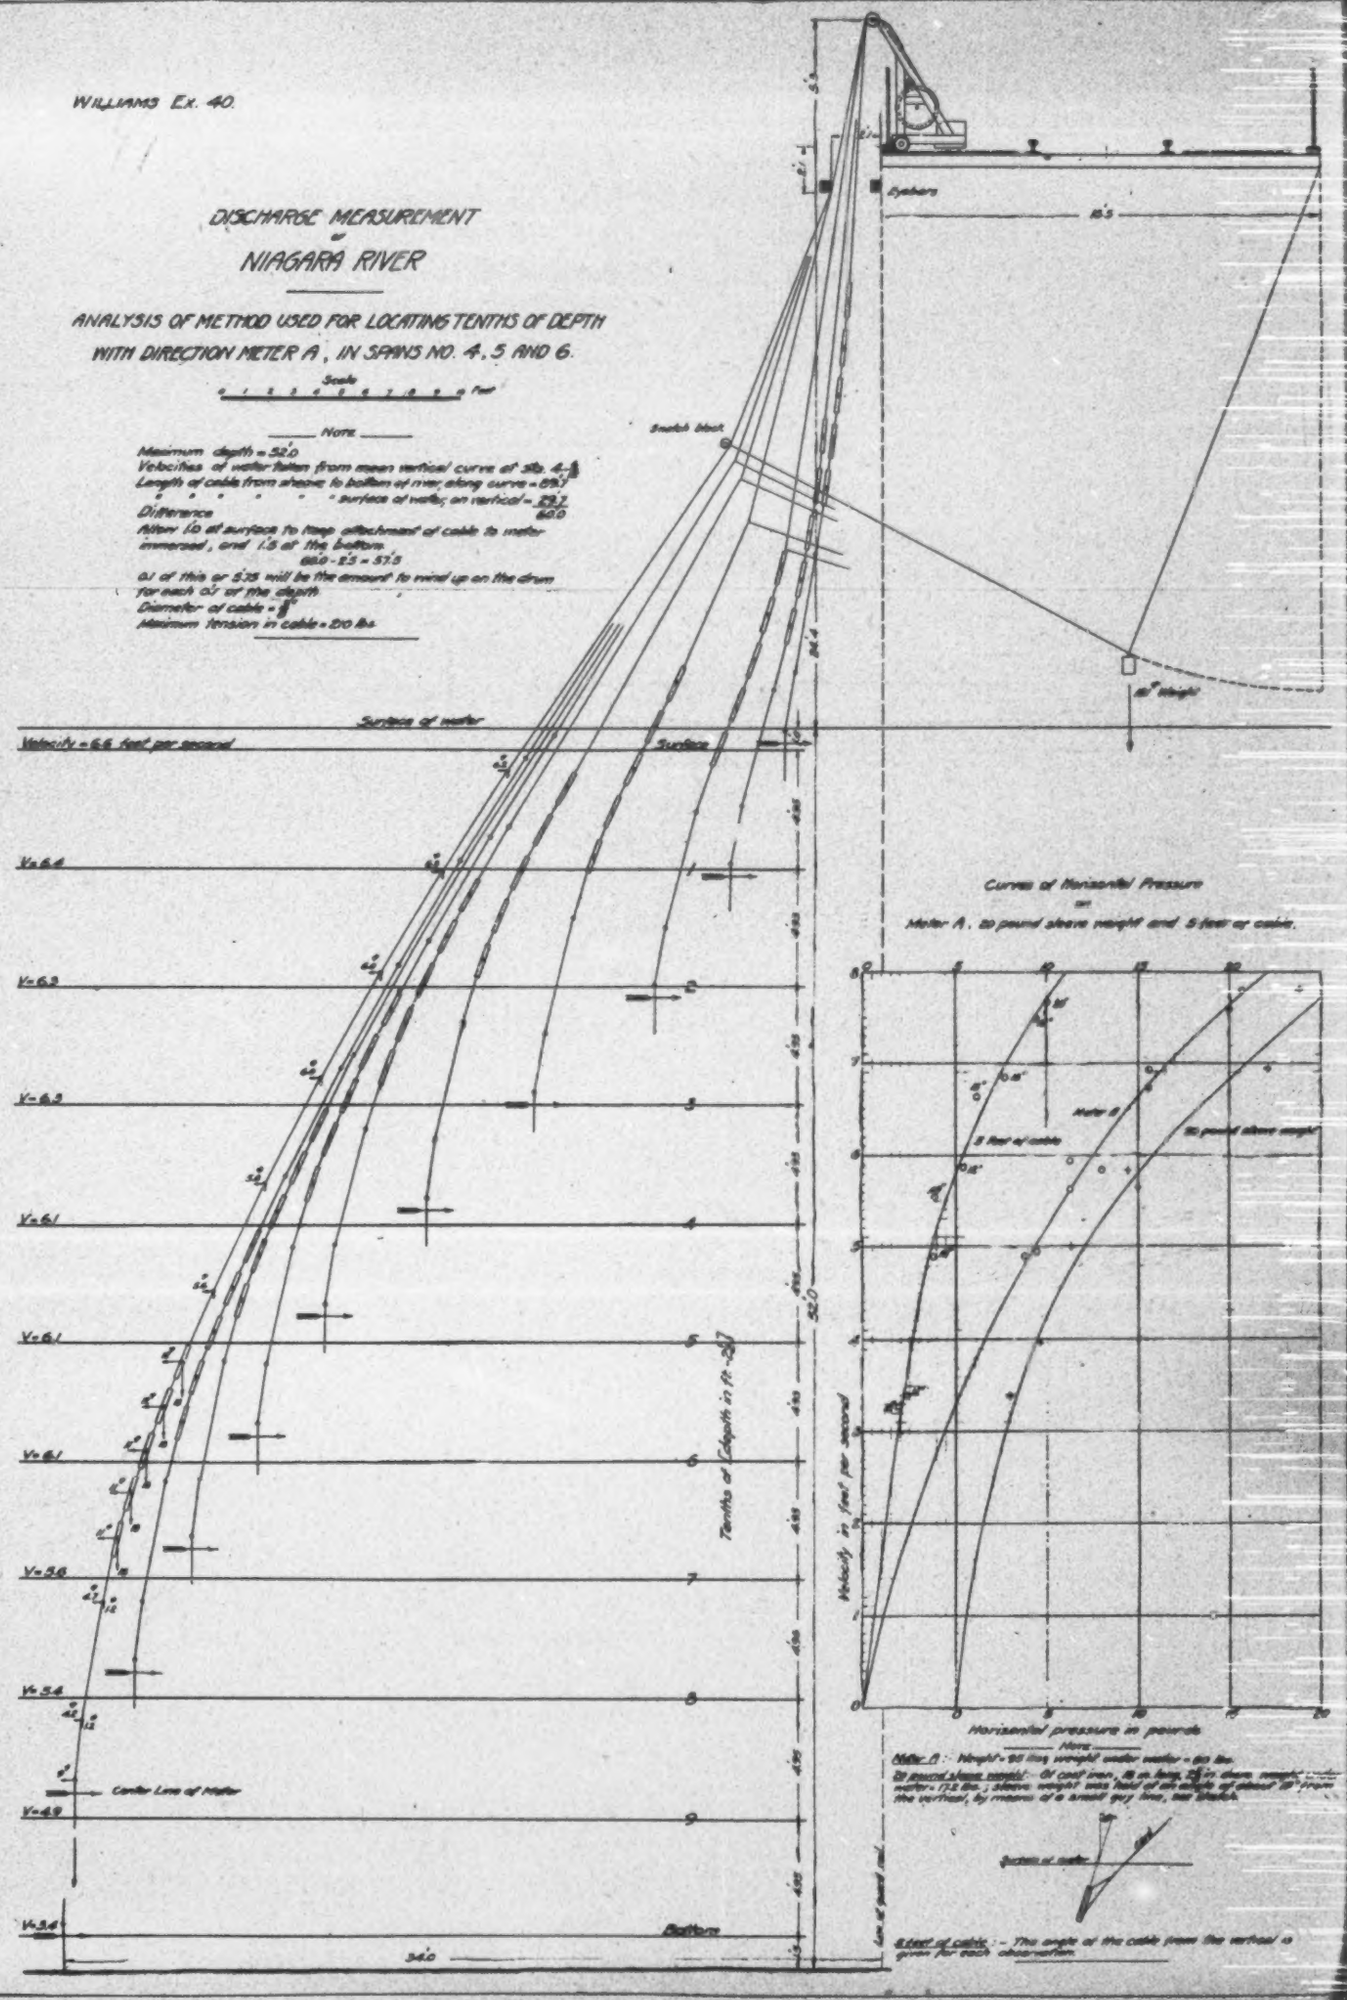
DISCHARGE MEASUREMENT
OF
NIAGARA RIVER

ANALYSIS OF METHOD USED FOR LOCATING TENTHS OF DEPTH WITH DIRECTION METER A, IN SPANS NO. 4, 5 AND 6.

Scale 0 1 2 3 4 5 6 7 8 9 10 Feet

Note

Maximum depth = 52.0
Velocities of water taken from mean vertical curve of Sts. 4-5
Length of cable from sheave to bottom of river along curve = 69.7
" " " " " surface of water, on vertical = 29.7
Difference 40.0
Allow 1.0 at surface to keep attachment of cable to meter immersed, and 1.5 at the bottom.
68.0 - 2.5 = 57.5
1/ of this or 5.75 will be the amount to wind up on the drum for each 1/ of the depth
Diameter of cable = 3/8"
Maximum tension in cable = 200 lbs.



PRESERVATION OF NIAGARA FALLS.

[fol. c] IN THE

CIRCUIT COURT OF THE UNITED STATES, NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

No. 29019

THE UNITED STATES OF AMERICA

vs.

THE SANITARY DISTRICT OF CHICAGO

BILL OF COMPLAINT—Filed March 23, 1908

[fol. 1] [Title omitted]

To the Honorable the Judges of the Circuit Court of the United States for the Northern District of Illinois, Eastern Division, in Chancery Sitting:

Your, orator, the United States of America, by Charles J. Bonaparte, its Attorney General, and Edwin W. Sims, its attorney for the Northern District of Illinois, brings this, its bill of complaint, against The Sanitary District of Chicago, the dlefendant, and respectfully alleges and represents unto your honors as follows:

First. That the defendant, The Sanitary District of Chicago, is a municipal corporation organized and existing under and by virtue of an act of the Legislature of the State of Illinois, approved May 29, 1889, in force July 1, 1889, and entitled, "An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illinois Rivers," that it has its principal office in the City of Chicago, in the State of Illinois, and that it is a citizen of the State of Illinois.

Second. That the Main Calumet River, situated in, and flowing, in a northeasterly direction through, the County of Cook, in the said State of Illinois, and emptying into Lake Michigan at South Chicago, [fol. 2] in said county, is a navigable river for its entire length from Lake Michigan to where it is formed by the Little and Grand Calumet rivers; that the United States has appropriated and expended large sums of money in improving the navigability of said river and in improving the harbor at the mouth of the same, that is to say, it has appropriated and expended in such improvement of said river, including its tributaries in Indiana and Illinois, between the years 1884 and 1907 inclusive, the sum of $994,218.98, and in the improvement of said harbor, since the year 1870, the sum of $1,567,230; that at the present time the largest vessels on Lake Michigan can enter said harbor and pass up said river for a distance of five miles, and small vessels can ascend the remaining three miles; that the Little Calumet

River, which, between the mouth of Stoney Creek and the mouth of said river, flows through the said County of Cook in an easterly direction, and in conjunction with the Grand Calumet River, in said county, forms the said Calumet River, is also a navigable river from its mouth to the mouth of Stoney Creek, in said county; that for all of that distance it has a depth of about 6 feet and steamboats and sailing vessels engaged in state and interstate commerce use said river for said distance; that the bridges across said river for said distance are provided with draws for the accommodation of such craft, and such bridges are under the direct supervision of the Secretary of War of the said United States; that the Grand Calumet River, an interstate stream rising in the State of Indiana and flowing in a northwesterly direction into and through the State of Illinois, to the said point of its conjunction with the Little Calumet River, is also a [fol. 3] navigable river, and the said United States has expended large sums of money in improving its navigability; that Lake Michigan and its harbor and connecting rivers and channels are navigable waters of the said United States; and that the United States has appropriated and expended large sums of money in improving the navigability of the rivers, channels and harbors connected with said Lake Michigan.

Third. That on the seventh day of December, in the year 1904, the Board of Trustees of the said The Sanitary District of Chicago duly passed an ordinance, which was afterwards duly approved by its president and which still remains in full force and effect, establishing and laying out a route for a channel and outlet of The Sanitary District of Chicago, to be known as the Calumet-Sag Channel, which said ordinance directed that said channel be constructed by the said Sanitary District from a point in the main channel of the said Sanitary District at a place called Sag, about 11 miles in a northerly direction up the said main channel from Lockport, in the State of Illinois, to a point in said Little Calumet River, at the mouth of Stoney Creek aforesaid, near the City of Blue Island (thereby connecting the said Little Calumet River with the said main channel of the said Sanitary District); that said ordinance provided that said channel should be constructed to a width of 90 feet at the bottom, with vertical sides, where the same is constructed through rock, and to a width of 70 feet on the bottom, with side slope of 3 feet vertical to 5 feet horizontal, where the same is constructed through earth, and that said channel should be constructed to a depth and on a grade sufficient to insure 22 feet depth of water flow; that the con- [fol. 4] struction and maintenance of said channel as provided for in and by the terms of said ordinance and as the defendant plans and proposes to construct and maintain the same, will result in reversing the flow of the said Little Calumet River and the said Calumet River in such a way as to make the water in those rivers flow out of Lake Michigan instead of into it, and as your orator is informed and believes, and so charges the fact to be, will result in diverting and abstracting from Lake Michigan a large quantity of water, to wit: 4,000 cubic feet of water per second and causing said water to flow through the said Calumet rivers into the said Calumet-Sag Channel,

through that channel into the main channel of said Sanitary District, and thence to the Desplaines, Illinois and Mississippi rivers, and on to the Gulf of Mexico.

Fourth. Your orator further represents, on information and belief, that such diversion and abstraction of the waters of Lake Michigan into the Mississippi River basin as aforesaid, will lower the level of the water in Lake Michigan, and thus diminish the navigable capacity and depth of the various rivers, channels and harbors connected therewith which have been deepened and improved at great expense under the authority of the Congress of the said United States. Such depths that the construction and maintenance of the said Calumet-Sag Channel and the diversion and abstraction of the proposed amount of water from Lake Michigan will have a tendency to undo and annul the orders of Congress as expressed in the various river and harbor acts appropriating funds for improving the harbors and channels connecting with Lake Michigan; that the construction and maintenance of the said Calumet-Sag Channel in [fol. 5] the manner that the defendant plans and proposes to construct and maintain the same, and the consequent and resultant diversion of the waters of Lake Michigan out of the Lake Michigan basin into the Mississippi basin as aforesaid, will alter and modify the condition and capacity of all the said harbors and of all the said channels (navigable waters of the said United States as aforesaid), and will impede, injure and obstruct navigation in many of said harbors and channels, and will create an obstruction to the navigable capacity of the last mentioned waters of the said United States.

Fifth. That the diversion of said water as herein above set forth and the creation of the said obstruction to the navigable capacity of the said navigable waters of the United States, as above described, by the defendant, has not been, and is not, affirmatively authorized by the Congress of the said United States, and has not been, and is not, authorized in any way by the said Congress.

Sixth. Your orator further represents, on information and belief, that the construction and maintenance of the said Calumet-Sag Channel, as the defendant plans and proposes to construct and maintain the same, will lower the levels of the water in the said Calumet, Little Calumet and Grand Calumet rivers, and will alter and modify the course, condition and capacity of those rivers respectively.

Seventh. Your orator further avers on information and belief, that the construction and maintenance of the said proposed Calumet-Sag Channel, as planned and proposed by the defendant, and its [fol. 6] consequent diversion of the waters of Lake Michigan out of the Lake Michigan basin into the Mississippi River basin as aforesaid, will lower the levels of the waters of said Lake Michigan and will injure and impede navigation in all of the harbors and channels in said waters.

Eighth. That in and by Section 10 of an act of Congress, approved Mar[illegible]h 3, 1899, and entitled, "An Act making appropriations

for the construction, repair and preservation of certain public works on rivers and harbors, and for other purposes," it is provided as follows:

"That the creation of any obstruction not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is hereby prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty, or other structures in any port, roadstead, haven, harbor, canal, navigable river or other water of the United States, outside established harbor lines, or where no harbor lines have been established, except on plans recommended by the Chief of Engineers and authorized by the Secretary of War; and it shall not be lawful to excavate or fill, or in any manner to alter or modify the course, location, condition, or capacity of any port, roadstead, haven, harbor, canal, lake, harbor of refuge, or inclosure within the limits of any breakwater, or of the channel of any navigable water of the United States, unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to the beginning of same";

which said law has remained and been in full force and effect ever since its passage and still remains in full force and effect.

Ninth. That heretofore, to wit, on or about the twenty-eighth day [fol. 7] of November, in the year 1906, the defendant made application to the Secretary of War of the said United States, for authority to construct and maintain the said Calumet-Sag Channel, as above described, and to reverse the flow of the said Calumet rivers, as above described; that thereafter the said Secretary of War requested the Chief of Engineers of the said United States to make his recommendation concerning the said application, and that thereupon, to wit, on the twenty-third day of February, in the year 1907, the said Chief of Engineers reported to the said Secretary of War that he was unwilling to recommend favorably the said proposed work; that thereafter, to wit, on the fourteenth day of March, in the year 1907, the said Secretary of War denied the said application and refused to authorize the said proposed work; and that up to the present time, to wit, the time of the filing of this bill of complaint, the said proposed work has not been recommended by the said Chief of Engineers and has not been authorized by the said Secretary of War, and still remains and is wholly without the recommendation, permission or approval of the said Chief of Engineers and still remains and is wholly without the authority, permission or approval of the said Secretary of War.

Tenth. That the defendant has announced its intention to construct and maintain the said proposed Calumet-Sag Channel, to reverse the flow of the said Calumet River and the said Little Calumet River as aforesaid, and to divert and abstract waters from Lake Michigan as aforesaid, notwithstanding the refusal of the said Chief of Engineers to recommend the same, and notwithstanding the re-

[fol. 8] fusal of the said Secretary of War to authorize the same, unless restrained by a court having jurisdiction to restrain said action, and to that end its Board of Trustees, on the eighteenth day of September, in the year 1907, adopted and passed an order, which is still in full force and effect, and a true copy of which is hereto appended, marked Exhibit "A," and made a part hereof.

Eleventh. Your orator further represents, upon information and belief, that the defendant desires, proposes and intends to divert the waters of Lake Michigan as aforesaid, through the said Calumet rivers and the Calumet-Sag Channel as aforesaid, for sanitary purposes and for the development of valuable water power which it proposes to sell; that the Congress of the United States has not fixed any amount of such waters for such proposed diversion, and has not provided for the diversion of any of such waters through the said Calumet rivers and the said Calumet-Sag Channel, and that the Secretary of War of the United States, under the direction of Congress, or in any other way, has not fixed any amount of such waters for such proposed diversion, but, on the contrary, has refused so to do, and has refused to authorize the diversion of any of such waters through said rivers and said channel.

Twelfth. Your orator further represents that the defendant cannot lawfully construct or maintain the said proposed Calumet-Sag Channel as above described, cannot lawfully reverse the flow of the said Calumet rivers as it plans and proposes to do as aforesaid, and cannot lawfully divert and abstract the waters of Lake Michigan as it plans and proposes to do as aforesaid.

[fol. 9] Thirteenth. That the defendant, on the sixteenth day of October, 1907, actually began the excavation of the said proposed Calumet-Sag Channel, at the westerly end of the same, with a force of men under the supervision of one William M. McCartney, its asistant engineer, and your orator is informed and believes, and so charges the facts to be, that the defendant intends to, and will, continue and complete the construction of said channel, reverse the flow of the said Little Calumet and the said Calumet rivers as aforesaid, and divert and abstract the waters of Lake Michigan as aforesaid, and maintain said channel as aforesaid, to the manifest and irreparable injury of your orator and its interstate navigation and commerce, unless restrained by the injunction of this honorable court.

Forasmuch, therefore, as your orator is remediless in the premises by the rules of the common law, and can have adequate relief only in a court of equity, and to the end that the said The Sanitary District of Chicago, a municipal corporation as aforesaid, which is made defendant to this your orator's bill of complaint, may full, true and perfect answer make to all and singular the matters and things hereinbefore stated and charged, but not under oath, its answer under oath being hereby expressly waived, your orator files this bill of complaint and prays your honors forthwith to grant a provisional

or preliminary writ of injunction directed to the said defendant, its Board of Trustees, officers, agents, attorneys, representatives, employes and servants, and all other persons, acting, or claiming or assuming to act, under its authority, enjoining it, and each of its Board of Trustees, officers, agents, attorneys, representatives, em- [fol. 10] ployes and servants, and each of the other persons aforesaid, from constructing, and from beginning or attempting to construct, and from continuing the construction of, and from doing anything in, towards, or about the construction of the said proposed Calumet-Sag Channel, and from constructing, and from beginning and attempting to construct, and from continuing the construction of, and from doing anything in, towards, or about the construction of, any channel, canal, ditch or drain, connecting the main channel of the Sanitary District of Chicago and with the said Little Calumet or with the said Calumet River or with Lake Michigan, of such a kind and character as to reverse the flow of said rivers or to divert or abstract any waters from Lake Michigan, and from doing or attempting anything in any way to connect the waters of the said Calumet rivers with the main channel of the said Sanitary District, and from doing or attempting anything in any way to reverse the flow of the said Calumet rivers, and from doing or attempting anything in any way to divert or abstract any waters from Lake Michigan in any channel other than the Chicago River as already authorized by the said Secretary of War, unless, prior to beginning any of said work, or doing or attempting to do any of such things, the Chief of Engineers of the said United States shall have recommended, and the Secretary of War of the said United States shall have authorized, the doing of such work, until such time as your honors shall appoint and direct for the final hearing herein, and upon such final hearing to make such injunction perpetual.

And may it please your honors to grant such other, further and [fol. 11] different relief in the premises as equity may require, and to your honors may seem meet.

And your orator prays that a writ of subpœna may issue to the said defendant. The Sanitary District of Chicago, commanding it, under a penalty and at a time and place to be therein stated, to appear and answer all and singular the matters hereinbefore stated and charged, and abide by and perform such orders as the court may make in the premises.

And your orator will ever pray.

Charles J. Bonaparte, Attorney General of the United States; By Direction of the Attorney General: Edwin W. Sims, United States Attorney for the Northern District of Illinois; James H. Wilkerson, Special Assistant United States Attorney, Solicitors for the United States.

[fol. 12] Jurat showing the foregoing was duly sworn to by W. H. Bixby omitted in printing.

[fol. 13] EXHIBIT A TO BILL OF COMPLAINT

Whereas, heretofore, to-wit: on the 7th day of December, A. D. 1904, by an ordinance duly passed by this Board and afterwards duly approved by its President, this Board established and laid out a route for a channel and outlet of the Sanitary District of Chicago, which channel was by said ordinance to be constructed and maintained, together with the necessary additions thereto, within the limits of said route, a map or plat of said route or right of way being attached to and made a part of said ordinance, entitled: "Sanitary District of Chicago, Ordinance Map for the right of way of the Calumet-Sag Channel from the westerly preserve line of the Illinois and Michigan Canal, in section 14, T. 37 N., R. 11, E. of the third principal meridian, to the north and south center line of section 32, T. 37 north, range 14, east of the third principal meridian," upon which said map or plat is shown the boundary line of the route for said channel, said boundary line being indicated in red on said plat and marked, "Ordinance Boundary Line," and

Whereas, By the terms of said ordinance it is provided that a channel be constructed by the Sanitary District of Chicago the center line of which shall begin at the center line of the main channel of the Sanitary District of Chicago, in section 14 township 37 north, range 11, east of the third principal meridian in Cook County, Illinois, at a point 707.55 feet, measured along the center line of said channel, distant from the westerly line of said section 14; running thence south 84 degrees east to the westerly reserve line of the [fol. 14] Illinois and Michigan Canal; thence along and upon the center line of the route established in and by the said ordinance; and

Whereas, The construction and maintenance of the channel provided for in and by the terms of said ordinance will result in diverting and reversing the flow of the Calumet river, a navigable stream now flowing into Lake Michigan, and,

Whereas, Heretofore, to wit, on November 28, A. D. 1906, this Board instructed its president to transmit to the Secretary of War an application for a permit to reverse the flow of said Calumet river and thereafter, to wit, on March 14, A. D. 1907, the Secretary of War communicated to this Board his refusal to issue such permit, and

Whereas, This Board is advised that it has the right and that it is its duty under the laws of the State of Illinois to construct its said channel and reverse the flow of said Calumet river, notwithstanding the refusal of the Secretary of War to issue a permit authorizing the same, for the purpose of furnishing the proper sanitary method of disposing of the sewage of the territory and inhabitants contiguous to the said proposed channel and within the corporate limits of the Sanitary District of Chicago, and unless restrained by a court having jurisdiction of the subject matter at the instance of the United States Government, and

Wheras, The Board of Trustees of the Sanitary District of Chicago deemed the construction of such channel and the reversal of the flow of said Calumet river necessary for the preservation of the health of a large number of persons residing within the limits of the [fol. 15] Sanitary District of Chicago; and that it is in duty bound under the law to proceed with the construction thereof, first giving notice of its intention so to do to the Secretary of War and to the Attorney General, that they may, if they see fit, take such steps as they think proper to protect the rights, if any, of the general government in the premises before the expenditure by the District of any considerable portion of the eight or ten millions of dollars necessary to construct the said channel, now, therefore, it is

Ordered, By the Board of Trustees of the Sanitary District of Chicago,

First. That the Finance Committee be, and it is hereby, instructed to forthwith negotiate for the purchase, upon such terms as said Finance Committee may deem just, of any and all property lying within said route for said channel, as described in the ordinance passed and adopted by this Board December 7, 1904, and that said Finance Committee, in the event it shall be unable to purchase any portion of said right of way, immediately instruct the Attorney of this District to institute proceedings in such court as he may deem proper for the condemnation of any of such property as said Finance Committee may be unable to purchase, or otherwise acquire, and,

Second. That the Chief Engineer be, and he is hereby instructed to forthwith prepare plans and specifications for the construction of said channel, according to the terms of the ordinance passed and adopted by this Board December 7, 1904, aforesaid, and that upon the acquirement of any property by the Finance Committee, as herein [fols. 16 & 17] directed, that the Chief Engineer be, and he is hereby instructed to install such machinery and employ such labor as may be necessary to immediately begin the construction of the said channel and secure the reversal of the flow of said Calumet river, and,

Third. That the Clerk of this District be, and he is hereby, instructed to transmit a certified copy of this preamble and order, together with a certified copy of the ordinance of December 7, 1904, aforesaid, and of the "Ordinance Map" attached thereto, to the Secretary of War, to the Attorney General of the United States, to the Chief of Engineers of the United States Army, and to Lieut. Col. Wm. H. Bixby, District Engineer in charge of the Chicago District, at Chicago, Illinois, said copies to be transmitted by United States mail, and the said Clerk is directed to report to this Board the manner in which he shall have carried out the terms of this order.

[File endorsement omitted.]

[fol. 18] IN THE CIRCUIT COURT OF THE UNITED STATES

[Title omitted]

[fol. 19] THE ANSWER OF THE SANITARY DISTRICT OF CHICAGO, RESPONDENT, TO THE BILL OF COMPLAINT OF THE UNITED STATES OF AMERICA, COMPLAINANT—Filed March 23, 1908

This respondent, the Sanitary District of Chicago, now and at all times hereafter, saving and reserving unto itself all benefit and advantage of exception which can or may be had or taken to the many errors, uncertainties and other imperfections in said bill contained, for answer thereunto, or to so much and such parts thereof as this respondent is advised it is or are material or necessary for it to [fol. 20] make answer unto, answering says:

First. This defendant admits that it is a municipal corporation, organized and existing under and by virtue of the laws of the State of Illinois, as charged in the first paragraph of the bill of complaint herein. This defendant hereto attaches a map or plat, marked "Exhibit A," made a part hereof, which represents and shows the territorial boundaries of this defendant, within which there is comprised substantially 358 square miles; that within the boundaries of said District there are situated the following cities, villages and towns: Chicago, Evanston, Glencoe, Winnetka, Wilmette, Shermerville, Glenview, Morton Grove, Miles, Cicero, Stickney, Evergreen Park, Morgan Park, Blue Island, Riverdale, Dolton, Harvey, West Hammond, Worth, Bremen and Calumet; that the population of said District exceeds 2,000,000.

Second. This defendant admits that the Calumet river is a river situated in the County of Cook and State of Illinois, flowing northeasterly, substantially as charged in paragraph two of the bill of complaint; and this defendant will hereinafter more particularly describe said river and attach plats showing the exact location and direction of the same; but this defendant expressly denies that said Calumet river is a navigable river for its entire course, as charged in said bill of complaint, but, on the contrary, alleges that the length, depth and width of said stream throughout its length is substantially as is hereinafter more particularly set forth in the twenty-second paragraph hereof. This defendant admits the allegations in said [fol. 21] paragraph two contained as to the amount of moneys appropriated and expended by the Federal Government in the improvement of said river.

This defendant denies that the Little Calumet river from its mouth to the conjunction thereof with Stony Creek is a navigable river; but, on the contrary, alleges that said river between said points is of the dimensions and capacity hereinafter more fully set forth in the twenty-second paragraph hereof.

This defendant further denies that said portion of said Calumet river above mentioned is traversed by any vessels whatsoever engaged in either interstate or intrastate commerce.

This defendant denies that the Grand Calumet river from its origin in the State of Indiana to its confluence with the Little Calumet is a navigable river within the meaning of that term.

Third. This defendant admits that on, to-wit, the 7th day of December, 1904, the Board of Trustees of the Sanitary District of Chicago passed an ordinance laying out a right of way for, and providing for the construction of, a channel or waterway substantially as set forth in paragraph 3 of the bill of complaint, a copy of which said ordinance is hereto attached, marked "Exhibit G" and made a part hereof as fully as if set forth herein.

This defendant alleges that afterwards on, to-wit, the 22nd day of January, 1908, said Board of Trustees passed another ordinance extending the right of way adopted December 7th, 1904, in an easterly direction from the point where it joined with the Little Calumet river, as provided for in said original ordinance, to a point known [fol. 22] as the "Forks" and shown on "Exhibit F" hereto attached, as will more fully appear from a copy of said ordinance attached hereto, made a part hereof and marked "Exhibit H."

This defendant denies the allegations made in paragraph 3 of the bill of complaint herein: that the construction of said waterway or channel as proposed will result in diverting and abstracting from Lake Michigan four thousand cubic feet of water per second; but on the contrary alleges that the amount of water that will be diverted or abstracted from Lake Michigan by reason of the construction of said channel or waterway will be as hereinafter more fully set forth.

Fourth. This defendant expressly denies the allegation contained in paragraph 4 of the bill of complaint herein that the diversion and abstraction of the waters from Lake Michigan contemplated by this defendant through its proposed channel and waterway will lower the level of the waters of the Great Lakes and will diminish the navigable capacity of said waters or the harbors thereof.

This defendant expressly denies that interstate or any other commerce will be, to any extent, injured or interfered with by the said diversion and abstraction of waters from the Great Lakes, or by the construction and maintenance of the Calumet-Sag Channel; and denies that the construction of said channel will have a tendency to undo and annul the orders of Congress, as expressed in its various river and harbor bills, appropriating funds for improving the rivers and harbors; and expressly denies that the construction of said water- [fol. 23] way and channel will alter and modify the conditions of the rivers and harbors of the United States, or any of them, and substantially and seriously impede, injure and obstruct the navigation of the Great Lakes, and the harbors and channels thereof, or the rivers flowing thereinto, as alleged in said paragraph 4; but, on the contrary, the defendant alleges that the construction and maintenance of said waterway and channel as proposed, and the diversion of water through the same as proposed, will not in any wise effect the navigable capacity of the Great Lakes, or the harbors and channels connected therewith, or the rivers flowing into the same, and will not interfere with, or in any degree injure, interstate commerce, or any

other commerce; but, on the contrary, as hereinafter shown, will be to the interest of interstate commerce and in accordance with the policy and laws of the United States.

Fifth. This defendant expressly denies the allegation contained in paragraph 5 of said bill of complaint, that the construction of said proposed channel has not been affirmatively authorized by the Congress of the United States; but, on the contrary, this defendant alleges that the construction and maintenance of the channel and waterway, substantially as it is proposed to be constructed, is expressly and affirmatively authorized and provided for by the statutes of the United States.

Sixth. This defendant denies the allegation in paragraph 6 of the bill of complaint, that the construction and maintenance of said proposed waterway will lower the level of the Little Calumet river; but [fol. 24] alleges that the effect upon said Little Calumet river that the construction and maintenance of said proposed waterway will have is fully set forth and shown hereinafter.

Seventh. This defendant admits that the various bodies of water mentioned in paragraph 7 of the bill of complaint are each connected with the other and are, in a measure, interdependent upon each other for their respective water levels; but this defendant expressly denies the allegation in said paragraph contained that the construction and maintenance of the proposed waterway, as planned by the defendant, and its consequent diversion of the water from Lake Michigan, would lower the levels of all of said waters, or any of them; and further expressly denies that such construction and maintenance of said channel would injure or impede navigation in the harbors and channels of said waters, or in any of them.

Eighth. This defendant further answering admits that Section 10 of an Act of Congress, approved May 3rd, 1899, is substantially as set forth in paragraph 8 of the complainant's bill herein; but this defendant denies that this act has any binding force on this defendant; or that said act in anywise prohibits the construction and maintenance of the channel or waterway proposed to be constructed by this defendant; or that the same is a constitutional or valid enactment.

Ninth. This defendant further answering admits that on or about the 28th of November, A. D. 1906, this defendant made application to the Secretary of War for a permit to reverse the flow of the Calumet [fol. 25] river, and that thereafter proceedings were had substantially as alleged by the complainant in paragraph 9 of this bill; but this defendant expressly denies that by said application it admitted the jurisdiction of the Secretary of War in such matters; or that it required such permit from said Secretary of War to construct and maintain said channel; but, on the contrary, alleges that it made such application to said Secretary of War purely as a matter of comity and in order to promote and maintain the spirit of harmony which it believed should obtain between the Federal Government

and the various state and local government of the United States; all of which more fully appears from a statement filed with the Secretary of War at the time of making said application, a part of which is in words and figures as follows, to-wit:

"That while insisting upon the right as a matter of right, we are entitled, nevertheless, to a permit from the Secretary of War; to evidence that there exists between the two governments that 'spirit of harmony and concilliation' which, in the words of Chief Justice Marshall, in Gibbons v. Ogden (9 Wheaton, 1), 'ought always to characterize the conduct of governments standing in the relation which that of the Union and those of the states bear to each other'; and to further evidence on the part of said governments that 'frank and candid co-operation for the general good' spoken of by Justice Johnson in the same case, 'which should always take place where there is a seeming blending of the power of the two governments and an apparent conflict.' "

Tenth. This defendant admits that through and by its Board of Trustees it adopted and passed an order substantially as set forth in paragraph 10 of the bill of complaint, and has announced its intention to construct and maintain said waterway and channel as [fol. 26] therein alleged, because of its belief that it has a lawful right to do so.

Eleventh. This defendant admits that Section 1 of an Act of Congress, approved June 29th, 1906, is substantially as set forth in paragraph 11 of complainant's bill of complaint; but this defendant denies that said law has any application to the work contemplated by this defendant, or that it has any binding force or effect in this case.

Twelfth. This defendant denies the allegation in paragraph 12 of complainant's bill of complaint, that the Congress of the United States has not provided for the diversion of any of the waters of Lake Michigan through said proposed waterway and channel; but, on the contrary, alleges that this defendant and the State of Illinois are expressly authorized by Congressional legislation to construct and maintain a waterway such as is proposed by the defendant and to divert the waters of Lake Michigan through the same into the Illinois river.

Thirteenth. This defendant denies that it cannot lawfully construct and maintain said proposed channel as alleged in paragraph 13 of the bill of complaint herein; but, on the contrary, alleges that it is lawfully empowered so to do, and that it is its duty so to do under the laws of the State of Illinois and of the United States.

Fourteenth. This defendant admits that on the 16th day of October, 1907, it actually began the work of excavating said proposed channel and the construction thereof, as alleged in paragraph 14 of the bill of complaint herein; and that it proposes to construct said [fol. 27] channel in the manner and form and of the character,

size and dimensions as hereinafter set forth; but this defendant expressly denies that the construction and maintenance thereof will be to the manifest or irreparable injury of the United States, or to interstate and foreign commerce; but, on the contrary, alleges that the construction and maintenance of said channel and waterway will benefit both state and interstate commerce.

Fifteenth. For further answer, this defendant says that in 1822 and in 1827 the Congress of the United States enacted laws authorizing the State of Illinois to construct a waterway suitable for navigation, connecting the waters of Lake Michigan with the waters of the Illinois river and to thereafter maintain the same at all times in a condition suitable for navigation, as will more fully appear from said acts, reference to which is hereby made. That after the passage of said acts by the Congress of the United States, the State of Illinois accepted the same and thereafter, by various acts duly passed by the General Assembly of said state, and approved by the governor thereof, the said state authorized the construction of, and did construct, and has ever since maintained, a waterway connecting the waters of Lake Michigan with the waters of the Illinois river, over and through which waterway commerce has been carried on continuously since the date of the completion thereof in, to-wit, 1848.

This defendant hereby refers to each and all of the several acts of the General Assembly of the State of Illinois relating to said waterway, which said acts are generally entitled "Acts relating to the [fol. 28] Illinois and Michigan Canal," and asks for the benefit thereof as fully as if set forth herein. This defendant further says that the waterway as originally constructed for the purpose of connecting the waters of Lake Michigan with the waters of the Illinois river, connected the waters of said lake with those of the Illinois river by a channel terminating at or near the City of Peru, on the Illinois river, in the County of La Salle and State of Illinois, and beginning at a point on the Chicago river, which in turn connected with Lake Michigan, in the City of Chicago, and also by a branch terminating at or near the mouth of Stony Creek, on the Calumet river, which said channel and which said branch connecting with said Calumet river are represented and shown on the map or plat which is hereto attached, marked "Exhibit E," by lines colored yellow.

Sixteenth. This defendant for further answer says that in compliance with and pursuant to the powers and duties resting upon this defendant under and by virtue of the several acts incorporating it heretofore referred to, this defendant has constructed a channel of the character and size and dimensions provided for by the original act of its incorporation, extending from a point on the Chicago river, in the City of Chicago, near the original termination of the Illinois and Michigan Canal, parallel with said Illinois and Michigan Canal, to and through the City of Joliet, as represented and shown upon said "Exhibit E" by lines colored red; that the construction of said channel was begun in the year 1892 and work thereon has proceeded continuously from that day to this and is, as yet, not entirely completed. Said channel was completed from its said connection with

[fol. 29] the Chicago river to a point at or near Lockport, a distance of 3 or 4 miles northeasterly from the City of Joliet, in the year 1900 sufficiently to turn the waters therein for the purpose for which said canal had been constructed; and that in the year 1900, pursuant to the various laws of the State of Illinois and the laws of the United States, this defendant did divert the waters of said Chicago river and Lake Michigan to and into said waterway and discharged the same therethrough into the Desplaines river and thence into the Illinois river; that since the turning in of said waters, this defendant has prosecuted the work of extending said canal from said point in Lockport to and through the City of Joliet and has likewise continued the work of deepening and widening the Chicago river with which it connects for the purpose of making said waterway sufficient to accomplish the objects of its creation, both as an outlet for the sewage of the Sanitary District and for the purpose of commerce and navigation; that said waterway or channel has been substantially completed from its connection with said Chicago river to the City of Joliet, a distance, approximately, of thirty-two miles; that from the point of its connection with the Chicago river for a distance of 7.8 miles said waterway is 110 feet wide on the bottom and 198 feet wide at the water line, with a depth of 22 feet of water; that for the next 5.3 miles it is 202 feet wide on the bottom and 290 feet wide at the water line, with a minimum depth of 22 feet of water; for the next 14.95 miles it is 160 feet wide on the bottom and 162 feet wide at the water line, with 22 feet depth of water, the same being cut through solid rock and glacial drift; for the next 2 miles its minimum [fol. 30] width is 160 feet at the bottom and it is irregular in width from there on, varying from 160 to 500 feet in width, with a minimum depth of 22 feet and maximum depth of 24 feet.

At this point there is a lock 130 feet long and 22 feet wide and 12 feet over mitre sills. Alongside this lock, there is a reservation for a lock of ample capacity to accommodate the largest lake-going vessels. For the next one mile, running southerly from said lock, the channel is 160 feet wide with a minimum depth of 19.7 feet; and for the next mile it is 160 feet wide with a minimum depth of 10 feet. That upon the construction of a large lock, provided for as aforesaid, the largest lake-going vessels will be able to pass through this channel from Lake Michigan to the City of Joliet. That the total amount expended by this defendant so far in the construction, operation and maintenance of said waterway to September 1, 1907, exceeded the sum of $54,500.000.00, which said sum, taken in connection with the amount theretofore expended by the State of Illinois in the construction and maintenance of the Illinois and Michigan Canal, exceeds, so this defendant is informed and believes, and upon such information charges the fact to be, the sum of $61,037,254.79.

Seventeenth. This defendant, further answering, says that after the turning in of the waters as aforesaid into the waterway constructed by this defendant as aforesaid, the City of Chicago, lying wholly within the confines of the territory embraced by this defendant, has so reconstructed and built its sewerage system, by a system of intercepting sewers and trunk sewers, as to carry the sewage of that portion

[fol. 31] of said city north of 87th street and south of Fullerton avenue into said channel, thus preventing the discharge thereof into Lake Michigan as the same had been wont theretofore to do and, in this manner, the said city has prevented the pollution of Lake Michigan and partially protected the water supply of said city, which is procured from said lake through water tunnels and intakes extending out a distance of four miles into the lake. The location of the intakes through which the City of Chicago obtains its water from Lake Michigan are represented and shown upon Exhibits "A" and "D," as thereon marked and indicated; and the territory within said city which is now discharging into this defendant's channel and waterway is represented upon "Exhibit D" by that space colored pink; that there has been constructed by the City of Chicago a trunk sewer or conduit from a point near the intersection of the shore line of Lake Michigan with 39th street westward to the south fork of the south branch of the Chicago river, through which said trunk sewer or conduit water from said Lake is forced by means of a pumping system, with a maximum capacity of said trunk sewer or conduit of 120,000 cubic feet per minute.

Eighteenth. This defendant, for further answer, says that the sewage from that portion of the territory of this defendant lying south of 87th street, and embracing the towns and territories as represented and shown upon "Exhibit D," still discharges into Lake Michigan, either directly or through the Calumet river; that the same pollutes the waters of the said lake and is a constant menace to the health of the people of said district, by reason of the fact that [fol. 32] it contaminates the waters of said lake in proximity to and around and about the so-called Hyde Park or 68th street intake, through which said intake a large proportion of the water supplying the inhabitants of the City of Chicago, and other municipalities within this defendant, is obtained.

This defendant is informed and believes, and upon such information charges the fact to be, that the water mains of the City of Chicago are so interdependent that the water entering any of the same may find its way into any and all portions of said city, and that the population of any one of the intakes of said city does or may pollute the water supply of said entire city and in this manner menaces and threatens the health and welfare of all the people of said community; that there is being discharged into said Lake Michigan the sewage of substantially 200,000 people residing south of said 87th street; that within said territory there are populous and rapidly growing cities, to wit, South Chicago, Pullman, West Pullman, Kensington and Harvey, together with several smaller towns and municipalities and a considerable portion of the City of Chicago.

Nineteenth. This defendant, further answering, says that it is for the purpose of protecting the water supply of its inhabitants from contamination by the sewage of the people living south of said 87th street, and for the purpose of complying with the duty resting upon it by the several laws of the State of Illinois, that it proposes to construct and maintain a waterway or channel, the construction of

which is sought to be enjoined by the bill of complaint herein; that [fol. 33] the authority of this defendant to construct said waterway or channel, and the purposes to be served by the construction and maintenance thereof, and the duty resting upon this defendant to construct the same, all fully appear from the several acts of the State of Illinois heretofore referred to. The said proposed channel, when completed, will be located as represented and shown on Exhibits "B" and "C"; that it will be substantially 21 miles in length, measuring from the eastern shore line of Lake Calumet along the line of said proposed waterway or channel to the connection thereof with the main channel at Sag; that said defendant proposes to construct and maintain a channel of the size, character and dimensions as follows, to wit: Beginning at the easterly termination thereof at a point indicated as the "Forks" in "Exhibit C" hereto attached, the outlet of Lake Calumet as shown on said exhibit, will be dredged 14 feet so as to give a depth to said outlet of 22 feet in place of the present depth of 8 feet. The bottom of said outlet as so dredged will have a width of 72 feet; the width at the water line will be not less than 160 feet. Running thence westerly through the southern portion of Lake Calumet one mile, dredging so as to create a channel having a width at the bottom of not less than 72 feet and a depth of not less than 20 feet, in place of the present depth of 4½ feet in said portion of Lake Calumet. From the westerly shore of Lake Calumet to a point on the Little Calumet river near 129th street one and one-quarter miles, the channel will be constructed 29 feet in depth with a width of 72 feet on the bottom and 160 feet at the water line, and depth of water of 22 feet. From the intersection of said channel with said Little [fol. 34] Calumet river, the channel of said river will be utilized as a section of said proposed waterway for a distance of approximately two miles to the confluence thereof with Stony Creek. Said section of said river so utilized will be dredged 12½ feet, giving a depth of water therein of 20 feet in place of the present depth of water therein of 10 feet. The width of said section of said river as so dredged at the bottom thereof will be 72 feet and the width thereof at the water line will be not less than 160 feet, or an average of 10 feet greater than the present average width of said section of said river. From the confluence of Stony Creek and the Little Calumet river, said channel will run in a westerly direction for a distance of approximately 16 miles through alternating sections of glacial drift and rock. Through glacial drift sections, said channel will be 72 feet wide at the bottom and 162 feet wide at the surface and 22 feet deep. Through rock sections, said waterway or channel will be 93 feet wide, with vertical sides, and depth of 22 feet. There will be constructed at the confluence of Stony Creek and the Little Calumet river a guard lock and controlling works through and by means of which this defendant will be able to control absolutely the quantity of water permitted to enter said channel and flow westwardly therethrough; that by the operation of the controlling works of this defendant it will be possible to prevent the flow of any water westwardly through said channel; that the maximum amount of water that it will be able

to flow westwardly through said channel will not exceed 4,000 cubic feet per second.

Twentieth. This defendant, further answering, says that upon [fol. 35] the completion of said channel, as proposed, this defendant proposes to flow westwardly through said channel waters sufficient to reverse the flow of the Calumet river in order to carry the sewage discharging therein through said channel and away from Lake Michigan, so that the same will no longer contaminate the water supply of the inhabitants of said district; but that the quantity of water so diverted will only be sufficient to cause a reversal of said flow and to properly dilute said sewage so as to comply with the several laws under which this defendant is incorporated, but that at no time would the amount of water so diverted through said channel exceed the amount of 4,000 cubic feet per second. That the maximum amount of water that can be flowed through the main channel of this defendant westwardly from the confluence of the proposed channel therewith is 840,000 cubic feet per minute; that the amount which this defendant flows therethrough, and will flow therethrough from time to time, will only be such an amount as is required by law for the proper dilution of the sewage of the district; and that the amount that this defendant does now and will thereafter flow, whether said proposed channel be constructed or not, will be said amount sufficient to dilute said sewage; that by the construction and maintenance of said proposed channel, it is not proposed by this defendant to flow any more than sufficient to meet the requirements of law to properly dilute the sewage of the district, which said amount it would be bound by law to flow through its main channel without the construction of the channel complained of by the complainant.

Twenty-first. For a further answer, this defendant says that it ex- [fol. 36] pressly denies that the construction and maintenance of said proposed channel would in any wise affect the levels of the Great Lakes and the channels, harbors and rivers connected therewith; or that it will in anywise injure, interfere with or be to the detriment of the commerce thereon; and this defendant expressly denies that the construction and maintenance of the proposed channel will in any wise affect the navigable capacity of the Little Calumet or Grand Calumet rivers, and alleges that it will not in any wise affect, alter, modify or change said Little Calumet river other than is herein specifically set forth, which this defendant alleges is to the benefit of said river and to the commerce thereon and not to the detriment thereof.

Twenty-second. And, further answering, this defendant says that "Exhibit F," a map or plat attached hereto and made a part hereof, shows in detail the depth, channel width and top width of the Calumet and Little Calumet rivers from Lake Michigan to Stony Creek as the same now exist; that the depth of Calumet river from Lake Michigan to 106th street is 21 feet, with a channel width of 200 feet

and a top width of from 225 to 300 feet; that from 106th street to 110th street said Calumet river has a depth of 20 feet, a channel width of 200 feet and a top width of from 230 feet to 250 feet; that from 110th street to 122nd street said Calumet river has a depth of 21 feet, a channel width of 200 feet and a top width of 250 feet; that from 122nd street to a point known as "Chittenden Bridge," designated upon said "Exhibit F" as Chittenden road, the said Calumet river has a depth of 17 feet, a channel width of 180 feet and a top [fol. 37] width of from 250 to 330 feet; that from said Chittenden bridge to a point shown upon said "Exhibit F" and designated as the "Forks," the said Calumet river has a depth of from 5 feet to 8 feet, a channel width of from 50 feet to 200 feet and a top width of 250 feet; that from the forks aforesaid to a point shown upon said "Exhibit F" and designated as the "Junction," being the confluence of the Grand Calumet and the Little Calumet rivers, the said river has a depth of 8 feet, a channel width of 60 feet and a top width of 112 feet; and that the Little Calumet river from the point designated upon said "Exhibit F" as the "Junction" to the confluence of Stony Creek and said Little Calumet river has a depth varying from 4 feet to 10 feet, a channel width of from 65 feet to 140 feet and a top width of from 105 feet to 270 feet.

Twenty-third. This defendant, further answering, says that upon the completion of the said channel as proposed it will afford navigation for vessels of the said Great Lakes through the Calumet river to its main channel and from thence to the City of Joliet and will be a sufficient and valuable route for commerce, both state and interstate, from Lake Michigan to the City of Joliet; that the construction and maintenance of said channel will be to the interest of the commerce of the Great Lakes and of the Desplaines, Illinois and Mississippi rivers; that all of the waters which this defendant now diverts from Lake Michigan, and which it proposes hereafter to divert through both its main and proposed channel, is discharged by this defendant into the Desplaines river and from thence into the Illinois river and forms through and by said rivers a navigable channel from [fol. 38] Lake Michigan to the Mississippi river and is to the interest of the commerce upon said rivers and to the commerce of the State of Illinois and of the United States; and that the construction and maintenance of the same by this defendant through and by authority of the State of Illinois is in accordance with the declared and express public policy both of the United States and of the State of Illinois, to forever maintain a waterway suitable for navigation connecting the waters of Lake Michigan with the waters of the Illinois and Mississippi rivers.

Twenty-fourth. This defendant further answering says that it is the only body or municipality clothed with authority to provide for the drainage and disposal of the sewage, and the furnishing of outlets for such outlets and sewage, within its corporate limits; that by reason of the laws of the State of Illinois, under and by virtue of which it exists, it is proceeding to dispose of and provide a means

for the disposal of, by a channel and adjuncts thereto, of all the sewage arising within its corporate limits which would otherwise flow into Lake Michigan, thus polluting the water supply of the inhabitants of this defendant; that the powers of this defendant and its authority in the matter of furnishing the outlets for the sewage and drainage of its territory, and the manner thereof, are circumscribed by the laws pursuant to which it is organized and existing; and that there is no other lawful method of disposing of the sewage and drainage of the territory comprised within the corporate limits of this defendant other or different than by the construction of channels and adjuncts thereto; and that the proposed channel complained of [fol. 39] by the complainant herein is a part of the only plan for the disposal of such sewage and the furnishing of outlets therefor which this defendant is empowered to carry out.

And this defendant, further answering, denies that the complainant is entitled to the relief, or any part thereof, in the said bill of complaint demanded, and prays the same advantage of this answer as if it had pleaded or demurred to the said bill of complaint; and prays that it be dismissed with its reasonable costs and charges in this behalf most wrongfully sustained.

The Sanitary District of Chicago, by John C. Williams, Its Solicitor. E. C. Lindley, Of Counsel.

[fol. 40] EXHIBIT G TO ANSWER

An ordinance for the establishment of a right of way for a channel from the westerly reserve line of the Illinois and Michigan Canal in Section 14, T. 37 N., R. 11 E., of the 3rd P. M., to the north and south center line of Section 32, T. 37 N., R. 14 E., of the 3rd P. M., and for the construction of a channel from the center line of the main drainage channel of the Sanitary District of Chicago, in said Section 14, T. 37 N., R. 11 E., of the 3rd P. M., to said center line of Section 32, T. 37, N., R. 14 E., of the 3rd P. M., in Cook County, Illinois.

Be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. That there be and is hereby laid out and established a route for a channel and outlet for the Sanitary District of Chicago, which channel is hereby directed to be constructed and maintained, together with the necessary additions thereto within the limits, of said route, which said route, shall be over, upon and through certain lands lying in the County of Cook and State of Illinois, and is described as follows, to-wit:

Beginning at the point of intersection of the westerly reserve line of the Illinois and Michigan Canal with the north and south center line of Section 14, T. 37 N., R. 11 E. of the 3d P. M.; running thence

south along said north and south center line of said Section 14 to a point 1,057.5 feet north of the center of said Section 14; thence southeasterly to the point of intersection of the east line of said Section 14 with the northerly reserve line of the Sag Feeder; thence along the northerly reserve line of said Sag Feeder to the north and south center line of Section 13, T. 37 N., R. 11 E. of the 3d P. M.; thence southeasterly to a point in the east line of Section 21, T. 37 N., R. 12 E. of the 3d P. M. 685.3 feet south of the northeast corner of said [fol. 41] Section 21; thence southeasterly to a point in the east line of Section 23, T. 37 N., R. 12 E. of the 3d P. M. 2,152.6 feet south of the northeast corner of said Section 23; thence southeasterly to the northwest corner of Section 29, T. 37 N., R. 13 E. of the 3d P. M.; thence east to the northwest corner of the N. E. ¼ of the N. W. ¼ of said Section 29; thence south along the west line of said N. E. ¼ of the N. W. ¼ of said Section 29 for a distance of 400 feet; thence southeasterly to a point in the north and south center line of said Section 29, 970 feet south of the north line of said Section 29; thence southeasterly to a point in the north line of the S. W. ¼ of the N. E. ¼ of said Section 29, 740 feet west of the northeast corner of said S. W. ¼ of the N. E. ¼ of said Section 29; thence east to the northeast corner of said S. W. ¼ of the N. E. ¼ of said Section 29; thence south along the east line of said S. W. ¼ of the N. E. ¼ of said Section 29 for a distance of 430 feet; thence southeasterly to a point in the east and west center line of the N. E. ¼ Section 33, T. 37 N., R. 13 E. of the 3d P. M. 510 feet west of the east line of said Section 33; thence south along said east line of said Section 33 for a distance of 640 feet; thence southeasterly to the northwest corner of the N. E. ¼ of the S. W. ¼ Section 34, T. 37 N., R. 13 E. of the 3d P. M.; thence southeasterly to a point in the north and south center line of said Section 34, 500 feet south of the east and west center line of said Section 34; thence southeasterly to a point in the north and south center line of the S. E. ¼ of said Section 34, 780 feet south of the east and west centre line of said Section 34; thence southeasterly to a point in the east line of said Section 34, 1,753.46 feet north of the southeast corner of said Section 34; thence east to a point in the north and south center line of Section 36, T. 37 N., R. 13 E. of the 3d P. M., 1,753.46 feet north of the south line of said Section 36; thence easterly to the northwest corner of Lot 20, Block 2, in Storz & Rhode's [fol. 42] Sub. of Lots 11, 12, 13 and 14 of Robinson's Subdivision, in the City of Blue Island; thence east along the north line of said Lot 20 to the west line of Lot 24, in said Block 2; thence north along the west line of said Lot 24 to the most northerly corner ther-of; thence southeasterly along the northe-ly line of said Lot 24; thence southeasterly along the northerly line of Lot 25 in said Block 2 for a distance of 40 feet; thence easterly to the north line of the east and west alley in Dornhecker's Sub. of Block 12, Robinson's Addition, in the City of Blue Island; thence east along the north line of said alley across Greenwood Avenue in said City of Blue Island and along the north line of the east and west alley in Dornhecker's Sub. of Block 11, Robinson's Addition to the southeast corner of Lot 1 in said Dornhecker's Sub. of Block 11; thence easterly to the most west-

erly corner of Lot 9, Block 10, Superior Court partition of Block 10, etc., in Robinson's Addition, in the City of Blue Island; thence northeasterly along the northwesterly line of said Lot 9 to the most northerly corner thereof; thence southeasterly along the northeasterly line of said Lot 9 to the most easterly corner thereof; thence northeasterly along the southeasterly lines of Lots 8 and 7 in said Block 10, to the most easterly corner of said Lot 7; thence easterly to the most northerly corner of Lot 7 in Bartelme's Sub. of Block 9, Robinson's Addition, in the City of Blue Island; thence southeasterly along the northeasterly line of said Lot 7 to the most easterly corner thereof; thence northeasterly to the northwest corner of Lot 4, Block 57, in Portland, a Subdivision in the City of Blue Island; thence east along the north line of said Lot 4, across Rexford Street, and along the north line of Lot 6, Block 56, in said City of Blue Island, to the west line of Lot 8 in said Block 56; thence north along the west line of said Lot 8 to the east and west center line of said Block 56; thence east along the east and west center line of said Block 56 across Gregory Street, along the east and west center line of Block 55, across [fol. 43] Wabash Street, along the east and west center line of Block 54, across Chatham Street, along the east and west center line of Block 53, and across Chicago Street, all in the City of Blue Island, to the east line of said Chicago Street; thence north along the east line of said Chicago Street to the southeast corner of said Chicago Street and Fulton Street; thence east along the south line of said Fulton Street and across State Street to the southeast corner of Fulton Street and State Street; thence north across said Fulton Street to the southwest corner of Keiffer's Addition to Blue Island; thence east along the south line of said Keiffer's Add. to Blue Island; to the west line of the north and south alley in said Keiffer's Add. to Blue Island; thence north along the west line of said alley to the northeast corner of Lot 12, in said Keiffer's Add.; thence east -cross said alley and along the north line of Lot 17 in said Keiffer's Addition to the west line of Robinson Street, in said City of Blue Island; thence north along said west line of Robinson Street to the south line of the east and west alley in said Keiffer's Addition; thence east across said Robinson Street to the most northerly corner of Block 49, in the City of Blue Island; thence southeasterly along the northeasterly line of said Block 49 to the most easterly corner of Lot 4 in said Block 49; thence easterly across Girard Street to the most southerly corner of Block 25 in said Portland, a Subdivision in said City of Blue Island; thence easterly to the southwest corner of Block 26, in said Portland, a Subdivision in the Town of Calumet; thence north along the west line of said Block 26 to the east and west center line thereof; thence east along the east and west center line of said Block 26 to the east line thereof; thence easterly across Colonade Row, in said Town of Calumet, to the Northwest corner of Lot 7, Block 27, in said Town of Calumet; thence east along the north line of said Lot 7 to the west line of Lot 4 in said Block 27; thence north along the west line of said Lot [fol. 44] 4 to the north line of said Block 27; thence east along the north line of said Block 27 and across Tremont Avenue to the southeast corner of Summit Street and Tremont Avenue; thence north

across Summit Street to the north line of said Summit Street; thence east along the north line of said Summit St. and across Exeter Street to the southwest corner of Block 6 in said town of Calumet; thence north along the west line of said Block 6 to the east and west center line thereof; thence east along said east and west center line of said Block 6 across Concord Street and along the north lines of Lots 6, 7 and 8, Block 5, in said Town of Calumet, to the west line of Lot 2 in said Block 5; thence north along the west line of said Lot 2 to the north line of said Block 5; thence east along the north line of said Block 5 across Portland Street to the northwest corner of Block 4 in said Town of Calumet; thence east along the north line of said Block 4 for a distance of 120 feet; thence northeasterly to a point in the west line of Section 31, T. 37 N., R. 14 E. of the 3d P. M. 160 feet north of the east ¼ corner of said Section 31; thence northeasterly to a point in the east line of the W. ½ of the S. W. ¼ of the N. W. ¼ Section 32, T. 37 N., R. 14 E. of the 3d P. M., 300 feet north of the east and west center line of said Section 32; thence east to a point in the north and south center line of said Section 32, 300 feet north of the center of said Section 32; thence south along the north and south center line of said Section 32 to the southeast corner of Block 159, in the Town of Calumet; thence southwesterly along the southeasterly line of said Block 159 to the most southerly corner thereof; thence northwesterly to the most southerly corner of Block 37, in the Town of Calumet; thence northwesterly along the southwesterly line of said Block 37, to the most westerly corner thereof; thence northwesterly to the most southerly corner of Block 36, in the Town of Calumet; thence westerly to the southeast corner of Block 38, [fol. 45] in the Town of Calumet; thence west along the south line of Block 38, across Cass Street, along the south line of Block 39, across Illinois Street, and along the south line of Block 40, all in the Town of Calumet, to the southwest corner of said Block 40; thence south across Randolph Street to the northwest corner of Block 73, in said Town of Calumet; thence west across Berrien Street to the northeast corner of Block 72 in said Town of Calumet; thence west along the north line of said Block 72 to the northwest corner thereof; thence westerly across Chadwick Street to the northeast corner of Lot 4, Block 71, in said Town of Calumet; thence south along the east line of said Lot 4 to the southeast corner thereof; thence west along the south line of said Lot 4 to the east line of Lot 6 in said Block 71; thence south along the east line of said Lot 6 to the southeast corner thereof; thence west along the south line of Lots 6, 7, 8, 9 and 10 in said Block 71 to the west line of said Block 71; thence south along the west line of said Block 71 to the southwest corner thereof; thence west across Duane Street and along the south line of Block 70 in said Town of Calumet to the southwest corner thereof; thence south across Sycamore Street to the northwest corner of Block 82, in the Town of Calumet; thence west across Portland Street to the northeast corner of Block 83, in said Town of Calumet; thence south along the east line of said Block 83 to the east and west center line thereof; thence west along said east and west center line, across Concord Street and along the east and west line of Block 45, in said

Town of Calumet, to the east line of said Block 45; thence south along the east line of said Block 45 to the southwest corner thereof; thence across Exeter Street and along the south line of Block 46, in said Town of Calumet, to the southwest corner thereof; thence south across Elm Street to the northwest corner of Block 88, in said Town of Calumet; thence west across Tremont Street and along the north line of Block 89, in said Town of Calumet, to the northwest corner [fol. 46] thereof; thence south along the west line of said Block 89 to the east and west center line thereof; thence west across Colonade Row and along the east and west center line of Block 90, in said Portland, a Subdivision in the Town of Calumet to the west line thereof; thence west to the point of intersection of the east and west center line of Block 91, in said Portland, a Subdivision in the City of Blue Island, with the east line of said Block 91; thence west along the east and west center line of said Block 91 to the west line thereof; thence south along the west line of said Block 91 to the southwest corner thereof; thence west across Robinson Street and along the south line of Block 92, in the City of Blue Island, to the southwest corner thereof; thence southwesterly to the northeast corner of Lot 4, Block 98, in the City of Blue Island; thence west along the north line of said Block 98, across Chicago Street, along the north line of Block 97, across Chatham Street, and across the north line of Rexford & Bellamy's re-sub. of Block 96, all in the City of Blue Island, to the northwest corner of said Rexford & Bellamy's re-sub.; thence south along the west line of said Rexford & Bellamy's re-sub. to the north line of the alley in said Rexford & Bellamy's re-sub.; thence westerly across Wabash Street to the point of intersection of the east and west center line of Block 95, in said City of Blue Island, with the east line of same; thence west along said east and west center line of said Block 95, across Gregory Street, and along the east and west center line of Block 94, in said City of Blue Island, to the east line of Lot 5 in said Block 94; thence north along the east line of said Lot 5 to the northeast corner thereof; thence west along the north line of said Lot 5 to the west line of said Block 94; thence westerly across Rexford Street to the northeast corner of Lot 2, in re-subdivision of Block 93, in said Portland, a subdivision in said City of Blue Island; thence west along the north line of said Lot 2 to the east line [fol. 47] of Lot 1, Block 17, in Assessor's Division of Blocks 17, 21, 22 and 25, in Robinson's Addition; thence south along said east line of said Lot 1 to the southeast corner thereof; thence east along the south line of said Lot 1 to the southwest corner thereof; thence northwesterly across Western Avenue, in the City of Blue Island, to the northeast corner of Lot 2, in subdivision of Block 18, Robinson's Addition; thence west along the north line of said Lot 2 to the northwest corner thereof; thence northwesterly to the northeast corner of Lot 2, Block 2, in Owner's Sub. of Block 20, and Lot 2, Block 19, in Robinson's Addition; thence west along the north line of said Lot 2 to the northwest corner thereof; thence westerly across Ann Street to the northeast corner of Lot 3, Block 1, in Owners' Sub. of Block 20, and Lot 2, Block 19, in Robinson's Addition; thence west along the north line of said Lot 3 across the north and south alley in said

Block 1, and along the north line of Lot 22 in said Block 1 to the west line of said Block 1; thence westerly to the northeast corner of Lot 6, in subdivision of Lot 6, Robinson's Subdivision, in City of Blue Island; thence westerly along the south line of Kott Street, across the north and south alley to the northwest corner of Lot 3 in said subdivision of Lot 6; thence westerly to the southeast corner of Block 4, Storz & Rhode's Subdivision of Lots 11, 12, 13 and 14 of Robinson's Subdivision; thence west along the south line of said Block 4, across Vine Avenue and along the south line of Block 3 in said Storz & Rhode's Sub. to the southwest corner thereof; thence westerly to a point in the north and south center line of Section 36, T. 37 N., R. 13 E. of the 3d P. M., 1093.46 feet north of the S. ¼ corner of said Section 36; thence west to a point in the west line of said Section 36, 1,093.46 feet north of the southwest corner of said Section 36; thence westerly to the southeast corner of Lot 46, Block 2; thence westerly along the south line of said Lot 46, across the alley [fol. 48] and along the south line of Lot 87, Block 2, across Sawyer Street, along the south line of Lot 168, Block 3, across the alley and along the south line of Lot 208, in said Block 3, across Spaulding Avenue, along the south line of Lot 288, Block 6, across the alley, along the south line of Lot 330 in said Block 6, across Turner Avenue along the south line of Lot 408, Block 7, across the alley, along the south line of Lot 449 in said Block 7 to the west line of said Block 7, all in Jas. J. Smith & Co.'s Second Addition to Clairmont, Lot 3 of Engelland's Sub. of E. ½, S. E. ¼, Sec. 35, T. 37 N., R. 13 E. of the 3d P. M.; thence westerly to a point in the west line of the East ½ of the S. E. ¼, Sec. 35, T. 37 N., R. 13 E. of the 3d P. M. 1,093.46 feet north of the south line of said Section 35; thence west to a point in the west line of said Section 35, 1,093.46 feet north of the southwest corner of said Section 35; thence northwesterly to the northwest corner of the S. ½ of the S. E. ¼, Section 34, T. 37 N., R. 13 E. of the 3d P. M.; thence north along the north and south center line of said Section 34 to a point 1,500 feet north of the S. ¼ corner of said Section 34; thence northwesterly to a point in the east line of the N. W. ¼ of the S. W. ¼ of said Section 34, 660 feet north of the east and west center line of said S. W. ¼ of said Section 34; thence northwesterly to the W. ¼ corner of said Section 34; thence northwesterly to a point in the north and south center line of the N. E. ¼ Section 33, T. 37 N., R. 13 E. of the 3d P. M., 2,000 feet south of the north line of said Section 34; thence northwesterly to a point in the north and south center line of the S. E. ¼ of Section 29, T. 37 N., R. 13 E. of the 3d P. M. 370 feet south of the east and west center line of said Section 29; thence northwesterly to a point in the east and west center line of said Section 29, 780 feet east of the center of said Section 29; thence west to the center of said Section 29; thence north along the north and south center line of said Section 29 for a distance of 540 feet; thence north- [fol. 49] westerly to a point in the south line of the N. W. ¼ of the N. W. ¼ of said Section 29; 900 feet east of the west line of said Section 29; thence west to the southwest corner of the N. W. ¼ of the N. W. ¼ of said Section 29; thence north on the west line of said

Section 29, 301 feet; thence northwesterly to a point in the west line of Section 24, T. 37 N., R. 12 E. of the 3d P. M. 3,162.4 feet south of the north line of said Section 24; thence northwesterly to a point in the west line of Section 22, T. 37 N., R. 12 E. of the 3d P. M. 1,702.7 feet south of the north line of said Section 22; thence northwesterly to a point in the south line of Section 17, T. 37 N., R. 12 E. of the 3d P. M. 1,441.9 feet east of the southwest corner of said Section 17; thence west to said southwest corner of said Section 17; thence north on the west line of said Section 17 for a distance of 261.8 feet; thence northwesterly to a point in the east and west center line of Section 14, T. 37 N., R. 11 E. of the 3d P. M., 200 feet east of the center of said Section 14; thence west along the east and west center line of said Section 14 to the westerly reserve line of the Illinois and Michigan Canal; thence northeasterly along said westerly reserve line of the Illinois and Michigan Canal to the point of beginning.

Section 2. That a channel be constructed by the Sanitary District of Chicago, the center line of which shall begin at the center line of the Main Channel of the Sanitary District of Chicago in Section 14, T. 37 N., R. 11 E. of the 3d P. M., in Cook County, Illinois, at a point 807.55 feet (measured along the center line of said Main Channel), distant from the westerly line of said Section 14; running thence south 84 degrees east to the westerly reserve line of the Illinois and Michigan Canal; thence along and upon the center line of the above established route. Said channel shall be constructed to a width of 90 feet at the bottom, with vertical sides—where the same is con-[fol. 50] structed through rock and said channel shall be constructed to a width of 70 feet on the bottom, *which* side slopes of three vertical to five feet horizontal, where the same is constructed through earth, and said channel shall be constructed to a depth and on a grade sufficient to insure a flow of 22 feet of water.

Section 3. The Finance Committee of the Board of Trustees of the Sanitary District of Chicago is hereby authorized and directed to negotiate for and to purchase for and on behalf of the Sanitary District of Chicago, upon such terms as said Finance Committee may deem just, any and all property, right of way and privilege within said route for said channel, as described in this ordinance; and in the event that said Finance Committee is unable to agree with any of the owners or parties in interest for any of said property or their interests therein, then, upon direction of said Finance Committee, the Attorney of the District shall institute proceedings in such court as he may deem proper for the condemnation of any such property, right of way or privilege as said Finance Committee is unable to acquire by purchase or otherwise.

Section 4. That attached hereto and made a part of this ordinance is a plat entitled "Sanitary District of Chicago, Ordinance Map for the Right of Way of the Calumet-Sag Channel, from the westerly reserve line of the Illinois and Michigan Canal, in Section 14, T. 37 N., R. 11, E. of the 3d P. M.," to the north and south center line of

Section 32, T. 37 N., R. 11, E. of the 3d P. M., upon which said plat or map is shown the boundary lines of the route for said channel, said boundary lines being indicated in red on said plat and marked "Ordinance Boundary Line."

Section 5. That an ordinance entitled "An ordinance for the establishment of a right of way for a channel from the westerly reserve line of the Illinois and Michigan Canal in Section 14, T. [fol. 51] 37 N., R. 13, E. of the 3d P. M., to the east line of the W. ½ of the N. E. ¼ of Section 23, T. 37 N., R. 13, E. of the 3d P. M., in Cook County, Illinois, and providing for the construction of such channel, passed May 4, 1904 (see pages 9908 and 9909 of Proceedings; and an ordinance entitled "An ordinance providing for the construction of a channel from the center line of the Main Channel of the Sanitary District of Chicago in Section 14, T. 37 N., R. 13, E. of the 3d P. M., to the east line of the west half of the N. E. ¼ of Section 23, T. 37 N., R. 13, E. of the 3d P. M., in Cook County, Illinois," passed July 20, 1904 (see pages 10056 and 10057 of Proceedings) be, and the same are hereby repealed.

Section 6. This ordinance shall be in force from and after its passage.

[fol. 52] EXHIBIT H TO ANSWER

An ordinance for the establishment of a right of way from the easterly end of the right of way established by the Board of Trustees December 7, 1904, to the north and south center line of section 25, T. 37 N., R. 14 E., of the 3rd P. M. and for the construction and maintenance of a channel from the north and south center line of frac. section 32, T. 37 N., R. 14 E., of the 3rd P. M. north of Indian boundary line to the north and south center line of sec. 25, T. 37 N., R. 14 E., of the 3rd P. M.

Be it ordained by the Board of Trustees of the Sanitary District of Chicago.

Section 1. That there be and is hereby laid out and established a route for a channel and outlet for the Sanitary District of Chicago, which channel is hereby directed to be constructed and maintained, together with the necessary additions thereto within the limits of said route, which said route shall be over, upon and through certain lands lying in the County of Cook and State of Illinois and is described as follows, to-wit:

Beginning at a point in the north and south center line of frac. sec. 32, T. 37 N., R. 14 E. of the 3rd P. M. north of Indian boundary line, 300 feet north of the center of said frac. sec. 32; thence northeasterly to a point in the west line of the W. ½ of the W. ½ of the N. E. ¼ of said frac. sec. 32, 680 feet north of the south line of said N. E. ¼ frac. sec. 32; thence northeasterly to a point in the west line of the E. ½ of said N. E. ¼ frac. sec. 32, 860 feet north of the

south line of said N. E. ¼ frac. sec. 32; thence northeasterly to a point in the west line of the east half of the E. ½ of said N. E. ¼ frac. sec. 32, 910 feet north of the south line of said N. E. ¼ frac. sec. 32; thence northeasterly to a point in the west line of frac. sec. [fol. 53] 33, T. 37 N., R. 14, E. of the 3rd P. M. north of the Indian boundary line, 925 feet north of the east and west center line of said frac. sec. 33; thence southeasterly to a point in the Indian boundary line 660 feet distant in southwesterly direction from the intersection of the north line of frac. sec. 33, T. 37 N., R. 14 E. of the 3rd P. M. south of Indian boundary line; thence easterly to a point in the easterly line of the right of way of the Pittsburgh, Cincinnati, Chicago & St. Louis Railway Co. 530 feet in southeasterly direction distant from said north line of frac. sec. 33; thence northeasterly to a point in said north line of said frac. sec. 33, 500 feet west of the N. E. corner of the N. W. ¼ of said frac. sec. 33; thence northeasterly to a point in the west line of the S. E. ¼ frac. sec. 28, T. 37 N., R. 14 E. of the 3rd P. M. south of Indian boundary line 760 feet north of the S. W. corner of said S. E. ¼ frac. sec. 28; thence northeasterly to the N. W. corner of lot 1, County Clerk's division of S. E. ¼ frac. sec. 28, T. 37 N., R. 14 E. of the 3rd P. M. south of Indian boundary line; thence southeasterly and easterly along the southerly line of 127th street to its intersection with the westerly line of the right of way of the Illinois Central Railroad Co.; thence northeasterly to a point in the east line of frac, sec. 27, T. 37 N., R. 14 E. of the 3rd P. M. south of Indian boundary line 2,030 feet north of the S. E. corner of said frac. sec. 27; thence north along the east line of said frac. sec. 27 to its intersection with the east and west center line of said frac. sec. 27; thence southeasterly to a point 1,321.24 feet west and 1,545 feet north of the S. E. corner of the S. W. ¼ sec. 25, T. 37 N., R. 14 E. of the 3rd P. M.; thence northeasterly to a point in the north and south center line of said section 25, 1,650 feet north of said S. E. corner of said S. W. ¼ sec. 25; thence south along said north and south center line of said sec. 25 for a distance of 660 feet; thence southwesterly to a point 875 [fol. 54] feet north and 1,321.24 feet west of said S. E. corner of said S. W. ¼ sec. 25; thence south on a line 1,321.24 feet west of and parallel to said north and south center line of said Sec. 25, to the south line of said sec. 25; thence westerly along the south line of said sec. 25 and the south line of sec. 26, T. 37 N., R. 14 E. of the 3rd P. M. to the easterly line of the right of way of the Michigan Central Railroad Co.; thence northwesterly along said easterly line of the right of way of the Michigan Central Railroad Co. for a distance of 1,680 feet; thence southwesterly to the S. W. corner of frac. sec. 27 T. 37 N., R. 14 E. of the 3rd P. M. south of the Indian boundary line; thence southwesterly to a point in the easterly line of the right of way of the Pittsburgh, Cincinnati, Chicago & St. Louis Railway Co., 1,140 feet in northwesterly direction distant from the north and south center line of frac. sec. 33, T. 37 N., R. 14 E. of the 3rd P. M. south of Indian boundary line; thence westerly to the point of intersection of the east and west center line of frac. sec. 32,

T. 37 N., R. 14 E. of the 3rd P. M. north of the Indian boundary line with said Indian boundary line; thence along said east and west center line of frac. sec. 33 to the west line of said frac. sec. 33; thence westerly along the south line of the N. E. ¼ frac. sec. 32, T. 37 N., R. 14 E. of the 3rd P. M. north of Indian boundary line to the east line of the W. ½ of the W. ½ of the N. E. ¼ of said frac. sec. 32; thence southwesterly to a point in the north and south line of said frac. sec. 32, said point being the southeast corner of block 159 in the town of Calumet; thence north along said north and south center line of said frac. sec. 32, to the point of beginning.

Section 2. That a channel be constructed by the Sanitary District of Chicago, the center line of which shall be, approximately, the center line of the above established route. Said channel shall [fol. 55] have a width of seventy-two feet at the bottom and shall be so constructed as to have a depth and grade sufficient to insure a flow of twenty-two feet of water.

Section 3. That attached hereto, and made a part of this ordinance, is a plat entitled "Sanitary District of Chicago. Ordinance Map for the Right of Way of the Calumet-Sag Channel from the North and South Center line of Sec. 32, T. 37 N., R. 14 E. of the 3rd P. M., to the North and South Center line of sec. 25, T. N., R. 14 E. of the 3rd P. M.;" upon which said map or plat is shown the boundary lines of the route for said channel, said boundary lines being indicated in red on said plat and marked "Ordinance Boundary Line."

plaint, but, on the contrary, alleges that the length, depth and width [fol. 64] of said stream throughout its length is substantially as hereinafter more particularly set forth in the twenty-second paragraph hereof,"

on the ground that the same is evasive and insufficient and does not fully, directly and completely respond to the allegations of the complainant's bill of complaint on the same subject, as contained in the second paragraph of the bill of complaint herein; and on the further ground that it appears from other portions of the answer of said defendant, to-wit, the allegations in the twenty-second paragraph of said answer, together with Exhibit F, annexed to said answer and made a part thereof, that said denial of the navigability of said Calumet river is untrue and that said portion of said answer above set forth is insufficient and impertinent; and on the further ground that it appears from the allegations in the bill of complaint, which are admitted by the defendant, and from the allegations in the answer of the defendant, and from the facts of which the court will take cognizance, that said Calumet river is a navigable river and is navigable water of the United States.

Second. The complainant excepts to the denial contained and purported to be made by said defendant in the second paragraph of its said answer, as follows, to-wit:

"This defendant denies that the Little Calumet river from its mouth to the conjunction thereof with Stony Creek is a navigable river; but, on the contrary, alleges that said river between said points is of the dimensions and capacity hereinafter more fully set forth in the twenty-second paragraph hereof,"

on the ground that the same is evasive and insufficient and does not [fol. 65] fully, directly and completely respond to the allegations of the complainant's bill on the same subject, as contained in the second paragraph of said bill; and on the further ground that it appears from the allegations in the bill of complaint which are admitted in the answer, and by the allegations in said answer, that said denial as to the navigability of said Little Calumet river is untrue, and that said denial is insufficient and impertinent; and on the further ground that it affirmatively appears from the allegations of the bill which are admitted and the allegations in the answer and from the facts of which the court will take cognizance that said Little Calumet river is a navigable river, and is navigable water of the United States.

Third. The complainant excepts to the denial contained and purported to be made by said defendant in the second paragraph of said answer, as follows, to wit:

"This defendant further denies that said portion of said Calumet river above mentioned is traversed by any vessels whatsoever engaged in either interstate or intrastate commerce,"

on the ground that same is evasive and insufficient and does not fully, directly and completely respond to the allegations of the bill of complaint on the same subject; and on the further ground that said defendant does not deny that the Calumet river is traversed by vessels engaged in interstate commerce, but on the contrary the fact that the said Calumet river is traversed by vessels engaged in interstate commerce is substantially admitted by aid answer, and that the facts with reference to the navigability and use of the Calumet river [fol. 66] as admitted by said defendant are sufficient for the purpose of granting the relief sought by the complainant.

Fourth. The complainant excepts to the denial contained and purported to be made by said defendant in the second paragraph of said answer, as follows, to-wit:

"This defendant denies that the Grand Calumet river from its origin in the State of Indiana to its confluence with the Little Calumet is a navigable river within the meaning of that term,"

on the ground that said denial is evasive, indefinite and does not completely respond to the allegations of the bill of complaint on the same subject; and on the further ground that said denial is shown by the other portions of said answer to be untrue.

Fifth. The complainant excepts to the denial contained and purported to be made by said defendant in the third paragraph of its answer, as follows, to-wit:

"This defendant denies the allegations made in paragraph 3 of the bill of complaint herein, that the construction of said waterway or channel as proposed will result in diverting and abstracting from Lake Michigan four thousand cubic feet of water per second,"

on the ground that said denial is evasive, insufficient, does not respond to the allegations of the bill of complaint on the same subject, and is shown by other portions of said answer to be untrue; and on the further ground that it affirmatively appears from other portions of said answer that a large quantity of water will be abstracted from Lake Michigan through the porposed channel, and that said statements in said answer are a practical admission of the allegations of [fol. 67] thebill of complaint as to the diversion of water from Lake Michigan.

Sixth. The complainant excepts to the denial contained and purported to be made by the defendant in the fourth paragraph of said answer, as follows, to wit:

"This defendant expressly denies the allegation contained in paragraph 4 of the bill of complaint herein, that the diversion and abstraction of the waters from Lake Michigan contemplated by this defendant through its proposed channel and waterway will lower the level of the waters of the Great Lakes and will diminish the navigable capacity of said waters or the harbors thereof,"

on the ground that said denial is evasive, insufficient, and does not fully, directly and completely respond to the allegations in the bill of complaint on the same subject, and that it appears from the allegations in the bill of complaint which are admitted by the defendant, and from the allegations in the answer of the defendant and from the facts of which the court will take cognizance, that said denial is untrue; and on the further ground that the finding and decision of the Secretary of War that the construction of said proposed channel and waterway will diminish the navigable capacity of Lake Michigan, and will alter and modify the condition and capacity thereof, is final and conclusive as against the defendant.

Seventh. The complainant excepts to the following portion of the fourth paragraph of said answer, to wit:

"This defendant expressly denies that interstate or any other commerce will be, to any extent, injured or interfered with by the [fol. 68] said diversion and abstraction of waters from the Great Lakes, or by the construction and maintenance of the Calumet-Sag Channel,"

on the ground that the same is impertinent and does not respond to any allegation in the bill of complaint, and that the matters therein set forth constitute no defense to the relief sought in the bill of complaint.

Eighth. The complainant excepts to the following portion of the fourth paragraph of said answer, as follows, to-wit:

"And denies that the construction of said channel will have a tendency to undo and annul the orders of Congress, as expressed in its various river and harbor bills appropriating funds for improving the rivers and harbors; and expressly denies that the construction of said waterway and channel will alter and modify the conditions of the rivers and harbors of the United States, or any of them, and substantially and seriously impede, injure and obstruct the navigation of the Great Lakes, and the harbors and channels thereof, or the rivers flowing thereinto, as alleged in said paragraph 4; but, on the contrary, the defendant alleges that the construction and maintenance of said waterway and channel as proposed, and the diversion of water through the same as proposed, will not in any wise affect the navigable capacity of the Great Lakes, or the harbors and channels connected therewith, or the rivers flowing into the same,"

on the ground that it appears from the other portions of said answer that each of the purported denials in the portion thereof last above set forth is untrue, and that said portion of said answer herein set forth is sham, evasive and insufficient, and does not fully and com- [fol. 69] pletely respond to the allegations of the bill of complaint on the same subject; and on the further ground that it affirmatively appears from the allegations of the bill which are admitted, and

from the allegations in the answer and from the facts of which the court will take cognizance that the construction of said proposed channel and waterway will affect the navigable capacity and condition of said Lake Michigan, and its harbors and channels, and the rivers flowing into it; and on the further ground that the finding and decision of the Secretary of War set forth in said bill and answer as to the effect of the construction and maintenance of said proposed waterway and channel is final and conclusive as against the defendant.

Ninth. The complainant excepts to the following portion of the fourth paragraph of said answer, to-wit:

"[The defendant alleges that the construction and maintenance of said water-way and channel as proposed] will not interfere with, or in any degree injure, interstate commerce, or any other commerce; but on the contary, as hereinafter shown, will be to the interest of interstate commerce and in accordance with the policy and laws of the United States,"

on the ground that the same is impertinent, does not respond to any of the allegations of the bill of complaint, is merely the statement of erroneous conclusions of law, and is shown by the allegations of the bill which are admitted and by the other allegations of the answer and by the facts of which the court will take cognizance to be untrue; and on the further ground that the finding and decision of the Secretary of War as set forth in the bill and answer are final and conclusive as against the defendant.

[fol. 70] Tenth. The complainant excepts to the allegations contained in the fifth paragraph of said answer on the ground that the purported denial therein is merely the statement of an erroneous conclusion of law; and on the further ground that there is no statute of the United States which authorizes and provides for the construction and maintenance of said channel and water-way, and that the allegation in said paragraph with reference to the existence of such a law is impertinent.

Eleventh. The complainant excepts to the allegations contained in the sixth paragraph of said answer for the reason that the same are insufficient, evasive, and do not fully and completely respond to the allegations of the bill of complaint on the same subject. The averment in the bill is that the construction and maintenance of said channel will lower the level of the Calumet, Little Calumet and Grand Calumet rivers; whereas the defendant in said answer merely denies that the construction of said channel will lower the level of the Little Calumet river. The defendant does not deny that the construction of said channel will alter and modify the course, condition and capacity of said rivers, as charged in said bill, but on the contrary it is admitted in said answer that the construction and maintenance of said channel will result in changing the course of said rivers.

Twelfth. The complainant excepts to the denial contained and purported to be made in the seventh paragraph of said answer, as follows, to-wit:

"This defendant expressly denies the allegation in said (7th) paragraph contained that the construction and maintenance of the pro- [fol. 71] posed water-way, as planned by the defendant, and its consequent diversion of the water from Lake Michigan, would lower the levels of all of said waters, or any of them; and further expressly denies that such construction and maintenance of said channel would injure or impede navigation in the harbors and channels of said waters, or in any of them,"

on the ground that the same is evasive, incomplete, and insufficient, and does not fully and completely respond to the allegations contained in the bill of complaint on the same subject; and on the further ground that it appears from the allegation of the bill which are admitted by the defendant, and from the allegations in the answer, and from the facts of which the court will take cognizance, that said purported denial is untrue, and that the effect of the construction and maintenance of said proposed channel will be necessarily to alter and modify the condition and capacity of said Lake Michigan; and on the further ground that the finding and decision of the secretary of war set forth in the bill, and answer, with reference to the effect of the construction of said proposed channel, are final and conclusive as against the defendant.

Thirteenth. The complainant excepts to the following portion of the eighth paragraph of said answer, as follows, to wit:

"This defendant denies that this act (the act of May 3, 1899) has any binding force on this defendant; or that said act in anywise prohibits the construction and maintenance of the channel or waterway proposed to be constructed by this defendant; or that the same is a constitutional or valid enactment,"

on the ground that the same is merely the statement of erroneous [fol. 72] conclusions of law, and is impertinent; and on the further ground that said act therein referred to is a valid and constitutional enactment, is binding upon the defendant, and prohibits the construction and maintenance of the channel and water-way proposed to be constructed by said defendant in the absence of the compliance by the defendant with the requirements and conditions therein set forth.

Fourteenth. The complainant excepts to the following portion of the ninth paragraph of said answer as follows, to wit:

"This defendant expressly denies that by said application it admitted the jurisdiction of the secretary of war in such matters,"

on the ground that it is merely the statement of an erroneous conclusion of law, and is impertinent; and on the further ground that

there is no proper denial of the specific allegations of the bill of complaint to the effect that said defendant did submit itself to the jurisdiction of said secretary of war for the purpose of the determination of the effect of the construction and maintenance of said proposed channel upon the condition and capacity of the navigable waters of the United States, described in said bill and answer.

Fifteenth. The complainant excepts to the following portion of the ninth paragraph of said answer, as follows, to wit:

"Or that it required such permit from said secretary of war to construct and maintain said channel,"

on the ground that the same is the statement of an erroneous conclusion of law, and is impertinent; and on the further ground that the construction of the proposed channel as described in said answer [fol. 73] would necessarily interfere with, alter and modify the condition and capacity of the navigable waters of the United States described in the bill and answer, and that the authorization by the secretary of war required by statute is a condition precedent to the lawful construction of said channel; and on the further ground that the finding and decision of said secretary of war, refusing to permit the construction of said proposed channel, are final and conclusive as against the defendant.

Sixteenth. The complainant excepts to the following portion of the ninth paragraph of said answer, to wit:

"But on the contrary, alleges that it made such application to said secretary of war purely as a matter of comity and in order to promote and maintain the spirit of harmony which it believed should obtain between the Federal Government and the various state and local governments of the United States; all of which more fully appears from a statement filed with the secretary of war at the time of making said application, a part of which is in words and figures as follows, to wit:

'That while insisting upon the right as a matter of right, we are entitled, nevertheless, to a permit from the secretary of war; to evidence that there exists between the two governments that 'spirit of harmony and conciliation' which, in the words of Chief Justice Marshal, in Gibbons v. Ogden (9 Wheaton, 1), 'ought always to characterize the conduct of governments standing in the relation which that of the Union and those of the states bear to each other'; and to further evidence on the part of said governments that 'frank and candid co-operation for the general good' spoken of by Justice [fol. 74] Johnson in the same case, 'which should always take place where there is a seeming blending of the power of the two governments and an apparent conflict,' "

on the ground that same is impertinent, and is not responsive to any of the allegations of the bill of complaint; and on the further ground that the matters therein set forth if true would not justify the wrongs alleged in the bill of complaint to have been committed

by the defendant, or in anywise constitute a defense against the relief sought by the bill of complaint.

Seventeenth. The complainant excepts to the following portion of the eleventh paragraph, to wit:

"But this defendant denies that said law has any application to the work contemplated by said defendant, or that it has any binding force or effect in this case."

on the ground that same is a mere statement of an erroneous conclusion of law and is impertinent; and on the further ground that it appears from the facts stated in the bill and admitted by the defendant, and from the allegations in the answer, and from the facts of which the court will take cognizance, that it is necessary for the construction of said channel to be authorized by the secretary of war, pursuant to statute; and on the further ground that said statute is a valid and constitutional enactment, and is applicable to the facts herein as admitted by the defendant.

Eighteenth. The complainant excepts to the allegations contained in the twelfth paragraph of the bill of complaint, on the ground that the purported denial therein involves the statement of an erroneous conclusion of law; and on the further ground that there is no congressional legislation authorizing the construction and [fol. 75] maintenance of said channel, and the diversion of the waters of said Lake Michigan, and that the averment in said paragraph to that effect is undue and impertinent.

Nineteenth. The complainant excepts to the thirteenth paragraph of said answer on the ground that it is merely the statement of an erroneous conclusion of law; and is impertinent; and on the further ground that there is no law authorizing the construction and maintenance of said proposed channel, and that the finding and decision of the secretary of war, made pursuant to statute, denying to the defendant the right to construct and maintain said proposed channel, are final and conclusive as to the defendant.

Twentieth. The complainant excepts to the following portion of the fourteenth paragraph of said answer, to wit:

"This defendant expressly denies that the construction and maintenance thereof will be to the manifest or irreparable injury of the United States, or to interstate and foreign commerce; but, on the contrary, alleges that the construction and maintenance of said channel and waterway will benefit both state and interstate commerce,"

on the ground that it appears from the allegations in the bill which are admitted by the defendant to be true, and from the allegations in the answer, that said purported denial is untrue, and that it is insufficient and impertinent; and on the further ground that the finding and decision of the secretary of war, with reference to the construction and maintenance of said channel, made pursuant to the statute, are final and conclusive against the defendant.

Twenty-first. The complainant excepts to all of the allegations [fol. 76] in the fifteenth paragraph of said answer on the ground that each of said allegations is impertinent; and on the further ground that said allegations, if true, would not justify the acts of the defendant charged in the bill, nor would they constitute a defense against the relief sought by the bill of complaint; and on the further ground that said allegations involve an erroneous construction of the statutes of the United States and erroneous conclusions of law.

Twenty-second. The complainant excepts to all of the allegations in the sixteenth paragraph of said answer on the ground that each of said allegations is impertinent, and has no relation whatever to any of the issues involved in this case, and that said allegations if true, would not justify the acts of the defendant charged in the bill of complaint, nor would they constitute any defense against the relief sought in said bill; and on the further ground that said allegations involve an erroneous construction and application of the statutes of the United States and of the State of Illinois.

Twenty-third. The complainant excepts to all of the allegations in the seventeenth paragraph of said answer on the ground that each of said allegations is impertinent and has no relation whatever to the issues involved in this case, and that said allegations if true, would not justify the acts of the defendant charged in the bill of complaint, nor would they constitute any defense to the relief sought in said bill; and on the further ground that said allegations involve an erroneous construction and application of the statutes of the United [fol. 77] States and of the State of Illinois.

Twenty-fourth. The complainant excepts to all of the allegations in the eighteenth paragraph of said answer on the ground that each of said allegations is impertinent, not responsive to any of the allegations in the bill of complaint, and in no way relates to any of the issues involved in this case; and that said allegations if true, would not justify the acts of the defendant charged in the bill of complaint, nor would they constitute any defense against the relief sought in said bill; and on the further ground that said allegations involve an erroneous construction and application of the statutes of the United States and of the State of Illinois.

Twenty-fifth. The complainant excepts to all of the allegations in the nineteenth paragraph of said answer on the ground that each of said allegations is impertinent, and is not responsive to any of the allegations in the bill of complaint, and does not relate in any way to the issues involved in this case, and that said allegations if true, would not justify the acts of the defendant charged in the bill of complaint, nor constitute a defense against the relief sought in said bill; and on the further ground that said allegations involve an erroneous construction and application of the statutes of the United States and of the State of Illinois.

Twenty-sixth. The complainant excepts to all of the allegations in the twentieth paragraph of said answer on the ground that each

of said allegations is impertinent, is not responsive to any of the [fol. 78] allegations in said bill of complaint, and does not in any way relate to the issues involved in this case, and that said allegations if true, would not justify the acts of the defendant charged in the bill of complaint, nor constitute a defense against the relief sought in said bill; and on the further ground that said allegations involve an erroneous construction and application of the statutes of the United States and of the State of Illinois.

Twenty-seventh. The complainant excepts to that portion of the twenty-first paragraph of said answer as follows, to wit:

"This defendant says that it expressly denies that the construction and maintenance of said proposed channel would in anywise affect the levels of the Great Lakes, and the channels and harbors and rivers connected therewith,"

on the ground that it appears from the allegations in the bill which are admitted by the defendant, and from the allegations in the answer herein, and from the facts of which this court will take cognizance, that said purported denial is untrue; and on the further ground that said portion of said paragraph is impertinent, insufficient and does not properly respond to any of the averments in said bill of complaint.

Twenty-eighth. The complainant excepts to the following portion of the twenty-first paragraph of said answer, to wit:

"Or that it will in anywise injure, interfere with or be to the detriment of the commerce thereon,"

on the ground that same is impertinent, is not responsive to any allegation in the bill of complaint, and is shown by the allegations [fol. 79] of the bill which are admitted, and by the allegations in the answer, to be untrue; and on the further ground that the finding and decision of the secretary of war with reference to the matters therein set forth, are final and conclusive against the defendant.

Twenty-ninth. The complainant excepts to the following portion of the twenty-first paragraph of said answer, to wit:

"And this defendant expressly denies that the construction and maintenance of the proposed channel will in anywise affect the navigable capacity of the Little Calumet, or Grand Calumet rivers, and alleges that it will not in anywise affect, alter, modify or change said Little Calumet river, other than as herein specifically set forth, which this defendant alleges is to the benefit of said river, and to the commerce thereon, and not to the detriment thereof,"

on the ground that the same is evasive, indefinite, insufficient, and does not fully respond to the allegations of the bill of complaint on the same subject; and on the further ground that it appears from the allegations of the bill which are admitted by the defendant, and from the allegations in the answer, that said purported denial is

untrue; and on the further ground that it affirmatively appears from the admissions in said answer that the effect of the construction of said channel will be to alter and modify and change the direction of the course of said Little Calumet river.

Thirtieth. The complainant excepts to all of the allegations in the twenty-third paragraph in said answer, on the ground that each of said allegations is impertinent, is not responsive to any allegation [fol. 80] in the bill of complaint, and does not relate in any way to the issues involved in this case; and on the further ground that the power to regulate commerce among the states is conferred, not upon the governments of the respective states, but upon the United States; that Congress in the exercise of its power has legislated with reference to the matters covered by the bill of complaint and the answer herein; that said legislation is valid, constitutional and binding upon the defendant, and that the effect of the construction of said proposed channel upon intestate commerce is a matter for determination, not by the authorities of the State of Illinois, but by the federal authorities, upon whom that power has been conferred by Congress.

Thirty-first. The complainant excepts to all of the allegations in the twenty-fourth paragraph of said answer, on the ground that each of said allegations is impertinent, and not responsive to any of the allegations in said bill of complaint, and that said allegations if true, would not justify any of the acts of the defendant complained of in the bill of complaint, nor constitute a defense against the relief sought in said bill; and on the further ground that it is not alleged in said paragraph, nor in any other portion of said answer, that the local government of Illinois could not make provision for the drainage and disposal of said sewerage in some adequate manner without violating the statutes of the United States, passed pursuant to the power to regulate commerce conferred upon Congress by the constitution, and without defying the lawful orders of the department of war made in the premises.

[fol. 81] Thirty-second. The complainant excepts to each and every one of the purported denials of the material allegations of the bill of complaint, on the ground that each of said purported denials is shown by the allegations of the bill which are admitted by the defendant, and by the other allegations of the answer, and by the facts of which the court will take judicial notice to be untrue, and is therefore insufficient; and on the further ground that there is no sufficient and complete denial of any one of the material allegations of said bill.

Thirty-third. The complainant excepts to said answer on the ground that there is no sufficient denial of the allegations in the bill of complaint to the effect that by the construction and maintenance of said proposed channel the defendant will divert a large quantity of water from Lake Michigan.

Thirty-fourth. The complainant excepts to said answer on the ground that there is no sufficient denial of the allegations of the bill to the effect that by the construction and maintenance of said proposed channel the defendant will alter and modify the course of the Calumet and Little Calumet rivers, and cause the water in said rivers to flow in a direction different from that in which it now flows.

Thirty-fifth. The complainant excepts to said answer on the ground that the defendant has not therein by sufficient averments denied the material allegations of said bill of complaint, entitling the complainant to the relief therein sought.

Thirty-sixth. The complainant excepts to said answer on the ground that it does not set up any matter constituting a defense to [fols. 82 & 83] the matters alleged in the bill of complaint.

Wherefore, the complainant comes and in all particulars aforesaid excepts to the answer of the said defendant on the grounds alleged, that the same is evasive, untrue, imperfect, insufficient, irrelevant, and impertinent; and prays that said irrelevant and impertinent portions of said answer hereinabove pointed out may be expunged from said answer, and that as to the remaining portions of said answer to which exceptions have been taken, said defendant may be compelled to put in a full, complete and sufficient answer with reference to the matters therein referred to; and that said complainant may have such other relief in the premises as to the court may seem proper.

Charles J. Bonaparte, Attorney-General of the United States; Edwin W. Sims, United States Attorney; James H. Wilkerson, Special Assistant United States Attorney, Solicitors for the United States.

[File endorsement omitted.]

[fol. 84] IN THE DISTRICT COURT OF THE UNITED STATES, NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

BILL OF COMPLAINT—Filed October 6, 1913

[fol. 85] To the Honorable the Judges of the District Court of the United States for the Northern District of Illinois, Eastern Division, in Chancery Sitting:

Your orator, The United States of America, by James G. McReynolds, its Attorney General, and James H. Wilkerson, its attorney for the Northern District of Illinois, brings this, its bill of complaint, against The Sanitary District of Chicago, defendant, and respectfully alleges and represents unto your Honors as follows:

First: That defendant, The Sanitary District of Chicago, is a municipal corporation, organized and existing under and by virtue of an act of the Legislature of the State of Illinois, approved May 29,1889, in force July 1, 1889, and entitled, "An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illinois Rivers"; that it has its principal office in the City of Chicago, in the State of Illinois, and that it is a citizen of the State of Illinois.

Second. That the Chicago river is situated in the County of Cook and State of Illinois and consists of a main river originally flowing in a generally easterly direction emptying into Lake Michigan, said main river being formed by two branches known as the north branch and the south branch of said Chicago river, and the said south branch being divided into two forks, known as the west fork and the south fork.

Third. That the said Chicago river, including both the north branch and the south branch, and the west fork and the south fork of the south branch, is a navigable water of the United States.

Fourth. That the United States has appropriated and expended a large sum of money, to wit, $4,216,066.36, in improving the navigability of said river and the harbor at the mouth of the same.

[fol. 86] Fifth. That in and by section 10 of an act of Congress, approved March 3, 1899, and entitled "An Act making appropriations for the construction, repair and preservation of certain public works on rivers and harbors, and for other purposes," it is provided as follows:

"That the creation of any obstruction not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is hereby prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty or other structures in any port, roadstead, haven, harbor, canal, navigable river, or other water of the United States, outside established harbor lines, or where no harbor lines have been established, except on plans recom-ended by the Chief of Engineers and authorized by the Secretary of War; and it shall not be lawful to excavate or fill, or in any manner to alter or modify the course, location, condition or capacity of any port, roadstead, haven, harbor, canal, lake, harbor of refuge or inclosure within the limits of any breakwater, or of the channel of any navigable water of the United States, unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to the beginning of the same."

which said law has remained and been in full force and effect ever since its passage and still remains in full force and effect.

Sixth. That heretofore, to wit, prior to the 8th day of May, 1899, defendant applied to the Secretary of War of the United States, for permission to reverse the current and the flow of the said Chicago

river and to divert and abstract a certain quantity of water from Lake Michigan through said Chicago river and through a certain canal which was constructed and being constructed by defendant; and thereafter, to wit, on the 8th day of May, 1899, the Secretary of War issued a permit to the defendant to reverse the current and flow of the said Chicago river and to divert and abstract from Lake Michigan not to exceed 300,000 cubic feet per minute, reserving the right to make such changes as the Secretary of War should see fit in the interests of navigation and property rights. A copy of said permit is attached hereto as Exhibit "A" and is referred to and made a part hereof with like effect as if set out in full herein.

Seventh. That thereafter, on, to wit, April 9, 1901, the Secretary of War ordered defendant to reduce the flow through the Chicago [fol. 87] river to 200,000 cubic feet per minute, a copy of which order is attached hereto as Exhibit "B" and is referred to and made a part hereof with like effect as if set out in full herein.

Eighth. That thereafter, defendant applied to the Secretary of War and in compliance with said application said Secretary of War, on, to wit, July 23, 1901, modified the permit and order theretofore issued and issued a permit to defendant to flow 300,000 cubic feet of water per minute between the hours of 4:00 P. M. and 12:00 P. M. midnight, a copy of which permit is attached hereto as Exhibit "C" and is referred to and made a part hereof with like effect as if set out in full herein.

Ninth. That subsequently thereto defendant applied for and obtained from the Secretary of War, on to wit, the 5th day of December, 1901, a permit to flow 250,000 cubic feet per minute throughout the twenty-four hours of the day, copy of which permit is attached hereto as Exhibit "D" and is referred to and made a part hereof with like effect as if set out in full herein.

Tenth. That subsequently thereto, defendant applied for and obtained from the Secretary of War, on, to wit, the 17th day of January, 1903, a permit to increase the flow through the Chicago river from 250,000 to 350,000 cubic feet per minute until the 31st day of March, 1903, after which date the flow to be reduced to 250,000 cubic feet per minute as theretofore, a copy of which permit is attached hereto as Exhibit "E" and is referred to and made a part hereof with like effect as if set out in full herein.

Eleventh. That subsequently, on, to wit, the 28th day of November, 1906, defendant made application to the Secretary of War for permission to construct a canal connecting the Calumet river with the main channel of the Sanitary District canal at what is known as Sag Station, and to reverse the flow of the Calumet river, and thereafter, on, to wit, the 14th day of March, 1907, the said Secretary of War denied the said application.

Twelfth. That subsequently thereto, defendant applied for and obtained from the Secretary of War, on, to wit, the 11th day of

September, 1907, a permit to construct a canal connecting Lake Michigan at Wilmette, Illinois, with the north branch of the Chicago river upon the condition that the total diversion of water from [fol. 88] Lake Michigan through the Chicago river should not exceed the amount already authorized by the War Department, to wit, 250,000 cubic feet per minute.

Thirteenth. That subsequently thereto, defendant applied for and obtained from the Secretary of War, on, to wit, the 27th day of June, 1910, a permit authorizing it to construct a canal connecting the Calumet with the main channel of the Chicago Drainage canal at Sag Station and to divert and abstract water from Lake Michigan through said canal, and providing, among other things, that the amount of water withdrawn from Lake Michigan through the Chicago river and the Calumet river together should not exceed the total amount of 250,000 cubic feet per minute, the amount previously authorized to be withdrawn through the Chicago river alone.

Fourteenth. That thereafter, on, to wit, the 5th day of February, 1912, defendant applied to the Secretary of War for permission to withdraw and divert from Lake Michigan through the Chicago river and Calumet river, not to exceed 10,000 cubic feet of water per second, or 600,000 cubic feet per minute, copy of which application is attached hereto, as Exhibit "F" and is referred to and made a part hereof with like effect as if set out in full herein.

Fifteenth. That thereafter, on to wit, the 8th day of January, 1913, the Secretary of War of the United States, refused said application of February 5, 1912, copy of which said refusal is attached hereto as Exhibit "G" and is referred to and made a part hereof with like effect as if set out in full herein.

Sixteenth. Your orator further represents that defendant has for a long period of time diverted and abstracted from Lake Michigan and caused to flow through the Chicago river and is at the present time diverting and abstracting from Lake Michigan and causing to flow through the Chicago river from 400,000 to 600,000 cubic feet of water per minute, which amount is greatly in excess of the amount so permitted to be diverted and abstracted from Lake Michigan to flow through the Chicago river by said Secretary of War as hereinbefore set out and is in direct violation of the permits of said Secretary of War which limits the said flow to 250,000 cubic feet per minute; that defendant plans, intends and threatens to continue to divert from Lake Michigan through the Chicago river from 400,000 to 600,000 cubic feet per minute in violation of the permits and orders of the Secretary of War.

Seventeenth. Your orator further represents that the Congress of the United States has not authorized the diversion of any of such [fol. 89] waters through the Chicago river, and that the Chief of Engineers has not recommended the said diversion of waters through the Chicago river in excess of 250,000 cubic feet per minute, nor

has the Secretary of War authorized the diversion of the waters of Lake Michigan through the said Chicago river in excess of 250,000 cubic feet per minute, but on the contrary has refused so to do, and has refused to authorize the diverson of any of such waters in excess of 250,000 cubic feet per minute through said river, as is more fully set out in paragraph fifteenth, hereof, and that the total amount of water which said defendant can legally divert or abstract from Lake Michigan in any manner cannot exceed 250,000 cubic feet per minute.

Eighteenth. Your orator further represents on information and belief that the diversion and abstraction of the waters of Lake Michigan into the Chicago river in excess of 250,000 cubic feet per minute has lowered and will continue to lower the level of the water of Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie, Lake Ontario, Sault Ste. Marie, St. Mary's river, St. Clair river, Detroit river, Niagara river, St. Lawrence river, and all the harbors, channels, canals and rivers connected therewith, all of which are navigable waters of the said United States, and will thus injure and diminish and create an obstruction to the navigable capacity of all said waters.

Nineteenth. That said waters have been deepened and improved under great expense of the United States under authority of the Congress of the United States, and that the diversion and abstraction of the waters of Lake Michigan in excess of the permits hereinbefore set forth, will have a tendency to undo and annul the orders of Congress as expressed in the various rivers and harbors acts appropriating funds for improving harbors and channels in the above named waters and channels connected therewith.

Twentieth. That the said diversion and abstraction of the waters of Lake Michigan through the Chicago river in excess of the permits of the United States as aforesaid, will alter and modify the condition and capacity of the channel of the said Chicago river which is a channel of a navigable water of the United States.

Twenty-first. That the said diversion and abstraction of the waters of Lake Michigan through the Chicago river in excess of the permits of the United States as aforesaid, will alter and modify the condition and capacity of Lake Michigan, Lake Huron, Lake St. [fol. 90] Clair, Lake Erie, Lake Ontario, Sault Ste Marie, St. Mary's river, St. Clair river, Detroit river, Niagara rivers and St. Lawrence river and the ports, roadsteads, havens, harbors, canals and harbors of refuge connected with the above named waters.

Twenty-second. Your orator further represents that defendant cannot lawfully continue to divert and abstract the waters of Lake Michigan as it now does and threatens to do as aforesaid without the recommendation of the Chief of Engineers of the United States and permission of the Secretary of War of the United States in excess of the permits hereinbefore referred to limiting the said flow to 250,000 cubic feet per minute, yet the defendant notwithstanding it has no right so to do, plans, intends and threatens to continue the diversion

of the waters of Lake Michigan in excess of the amount so permitted and authorized by the Secretary of War, to the manifest and irreparable injury of your orator and its interstate navigation and commerce, unless restrained by the injunction of this Honorable Court.

Forasmuch, therefore, as your orator is remediless in the premises by the rules of the common law, and can have adequate relief only in a court of equity, and to the end that the said Sanitary District of Chicago, a municipal corporation as aforesaid, which is made defendant to this your orator's bill of complaint may full, true and perfect answer make to all and singular the matters and things hereinbefore stated and charged (but not under oath, its answers under oath being hereby expressly waived), your orator files this bill of complaint and prays your Honors forthwith to grant a provisional or preliminary writ of injunction directed to the said defendant, its Board of Trustees, officers, agents, attorneys, representatives, employees and servants, and all other persons, acting, or claiming or assuming to act, under its authority, enjoining it, and each of its Board of Trustees, officers, agents, attorneys, representatives, employes and servants, and each of the other persons aforesaid, from diverting or abstracting any waters from Lake Michigan over and above and in excess of 250,000 cubic feet per minute as already authorized by said Secretary of War until such time as your honors shall appoint and direct for the final hearing herein, and upon such final hearing to make such injunction perpetual.

And may it please your honors to grant such other, further and different relief in the premises as equity may require and to your honors may seem meet.

[fol. 91] And your orator prays that a writ of subpœna may issue to the said defendant, The Sanitary District of Chicago, commanding it, under a penalty and at a time and place to be therein stated, to appear and answer all and singular the matters hereinbefore stated and charged, and abide by and perform such orders as the court may make in the premises.

And your orator will ever pray.

James C. McReynolds, Attorney General of the United States.
By Direction of the Attorney General: James H. Wilkerson, United States Attorney for the Northern District of Illinois.

[fol. 92] EXHIBIT "A" TO BILL OF COMPLAINT

"Whereas, by Section 10 of an act of Congress approved March 3, 1899, entitled 'An Act making appropriations for the construction, repair and preservation of certain public works, on rivers and harbors, and for other purposes,' it is provided that it shall not be lawful to alter or modify the course, location, condition or capacity of the channel of any navigable water of the United States unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same:

And whereas, the Sanitary District of Chicago, a municipal corporation, organized under the laws of the State of Illinois, has constructed an artificial channel from Robey street, Chicago, to Lockport, and has been heretofore granted permission by the Secretary of War to make certain improvements in the Chicago river for the purpose of correcting and regulating the cross section of the river so as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles an hour, it being intended to connect the said artificial channel with the west fork of the south branch of Chicago river at Robey street in the said City of Chicago.

And whereas, The said Sanitary District of Chicago has now applied to the Secretary of War for permission to divert the waters of the said Chicago river and cause them to flow into the said artificial channel at Robey street as aforesaid;

And whereas, The said Sanitary District of Chicago represents that such movable dams and sluice gates as are necessary to, at all times, secure absolute and complete control of the volume and velocity of flow through the Chicago river have been constructed;

Now therefore, The Chief of Engineers having consented thereto, this is to certify that the Secretary of War hereby gives permission to the said Sanitary District of Chicago to open the channel constructed and cause the water of Chicago river to flow into the same, subject to the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and [fol. 93] final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it become apparent that the current created by such drainage works in the south and main branches of Chicago river, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago river and its South Branch.

3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago river.

Witness my hand this 8th day of May, 1899.

R. A. Alger, Secretary of War. (Seal War Office.) John M. Wilson, Brig. Genl. Chf. of Engrs. U. S. A."

EXHIBIT "B" TO BILL OF COMPLAINT

"Whereas, under date of May 8th, 1899, the Secretary of War granted permission unto The Sanitary District of Chicago to open the artificial channel from Roby Street, Chicago, to Lockport, and

cause the waters of Chicago river to flow into the same, upon the following condition, inter alia:

'2. That if, at any time, it becomes apparent that the current created by such drainage works in the south and Main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south Branch.'

And whereas, It is alleged by various commercial and navigation interests that the present discharge from the river into the Drainage Canal sometimes exceeds three hundred thousand (300,000) cubic feet per minute, causing a velocity of nearly three (3) miles per hour, which greatly endangers navigation, in the present condition of the river.

Now, therefore, This is to certify that the Secretary of War, upon the recommendation of the Chief of Engineers, hereby directs said [fol. 94] Sanitary District to regulate the discharge from the river into the Drainage Canal so that the maximum flow through the Chicago river and its south branch shall not exceed two hundred thousand (200,000) cubic feet per minute.

Witness my hand this ninth day of April, 1901.

Elihu Root, Secretary of War."

"EXHIBIT "C" TO BILL OF COMPLAINT

"War Department, Washington

File No. 2560 of 1900.

July 23, 1901.

SIR: Referring to War Department order of April 9th last, restricting the flow of water through the Chicago River under War Department permit of May 8, 1899 to 200,000 cubic feet per minute, and replying to your letter of the 15th instant, in which you request, for reasons stated, that the said order be amended to permit a flow of 300,000 cubic feet per minute between the hours of 4 P. M. and twelve o'clock midnight, I beg to inform you that I have this day approved the modification last referred to, which approval will be subject to revocation by the Department in case the increase shall prove to be dangerous to nagivation.

Very respectfully, Elihu Root, Secretary of War. Mr. Alexander J. Jones, President Sanitary District of Chicago, Chicago, Illinois."

EXHIBIT "D" TO BILL OF COMPLAINT

"J. A. G. O. (6353)

Whereas, Under date of May 8th, 1899, the Secretary of War granted permission unto the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of Chicago River to flow into the same, upon the following condition, inter alia;

[fol. 95] "2. That if, at any time, it becomes apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch;"

And whereas, The Secretary of War subsequently directed said Sanitary District of Chicago, to regulate the discharge of water into the Chicago Drainage Canal so that the maximum flow through the Chicago River shall not exceed 200,000 cubic feet per minute from midnight to 4 p. m., nor 300,000 cubic feet per minute from 4 p. m. to midnight;

And whereas, Said Sanitary District of Chicago has applied to the Secretary of War for permission to increase the flow between midnight and 4 p. m. daily, to 250,000 cubic feet per minute; and the Chief of Engineers has recommended that the increase applied for be granted, but that the rate of flow from 4 p. m. to midnight be reduced to 250,000 cubic feet per minute, so that flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day.

Now, therefore, This is to certify that, in accordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto the said Sanitary District of Chicago permission to regulate said discharge so that the maximum flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day, upon the following conditions:

1. That this permission shall be in lieu of the present authorized rates of flow as stated above.

2. That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

3. That said Sanitary District of Chicago shall be responsible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

Witness my hand this 5th day of December, 1901.

W. Cary Sanger, Assistant Secretary of War."

[fol. 96] EXHIBIT "E" TO BILL OF COMPLAINT

"J. A. G. O. (6353)

Whereas, under date of December 5, 1901, by an instrument supplementary to the original permission granted by the Secretary of War, May 8, 1899, to the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of the Chicago River to flow into the same, the Secretary of War, pursuant to authority reserved in said permission of May 8, 1899, gave permission to the Sanitary District of Chicago to regulate said discharge so that the maximum flow per minute throughout the twenty-four hours of the day, upon the following conditions, inter alia:

"That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require";

And whereas, The said Sanitary District of Chicago has applied for permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute during the closed season of navigation, in order to carry off the accumulations of sewage deposit which line the shores along the city;

Now, therefore, This is to certify that, in accordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto said Sanitary District of Chicago permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute, until the 31st day of March, 1903, after which date it shall be reduced to 250,000 cubic feet per minute, as now authorized, upon the following conditions:

1. That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

2. That said Sanitary District of Chicago shall be responsible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

Witness my hand this seventeenth day of January, 1903.

W. Cary Sanger, Assistant Secretary of War."

[fol. 97] EXHIBIT "F" TO BILL OF COMPLAINT

"The Sanitary District of Chicago

Chicago, February 5th, 1912.

SIR: On behalf of the Board of Trustees of The Sanitary District of Chicago, I have the honor to apply for enlargement of the terms

of an instrument executed by The Secretary of War May 8, 1899, as modified by instruments similarly executed on December 5, 1901, and June 30, 1910, respectively, in the following particulars and in view of the facts hereinafter set forth, to wit:

The flow of water from Lake Michigan through the canal of The Sanitary District of Chicago is now limited by the said instruments to 4167 cubic feet per second.

The population of the Sanitary District, the sewage of which is to be disposed of through the channels constructed and to be constructed by the said District, exceeds 2,500,000 persons, and is rapidly increasing. The only method at present available for disposing of the sewage of this population is by diluting the same with water withdrawn from Lake Michigan and flowing through the Chicago Drainage Canal. The least amount of water necessary to render sewage innocuous by the dilution method has been estimated by well recognized sanitary experts as 1,000 feet per second for every 300,000 inhabitants; so that the amount permitted to be withdrawn by the instruments to which reference has been made is much below the amount at present needed by the District.

The Sanitary District has been for some time engaged in investigating methods and devising plans for the treatment of the sewage with a view to requiring less water for its safe dilution in the future. The methods of other states and countries for such treatment of sewage, are not as yet entirely satisfactory to all concerned, and any changes of methods for large cities must necessarily require several years.

Until these experiments are concluded and proper works installed, the use of additional water from Lake Michigan is essential to the health of the large population of the City of Chicago and of the Sanitary District and of those who live adjacent to the Des Plaines and Illinois rivers into which such waters are discharged.

Subject therefore to such restrictions as to you may seem proper [fol. 98] for the protection of the public interest, and to such a method of supervision as you may suggest to promote the general welfare, and pending the completion of the investigations now being conducted to render the use of increasing quantities of water in the future necessary; I have the honor to apply for permission for The Sanitary District of Chicago to withdraw from Lake Michigan through the Chicago river and Calumet river—not to exceed ten thousand cubic feet of water per second; such permission to be revocable at any time by The Secretary of War, and subject to such action as the Congress of the United States may see fit to take in the premises.

Respectfully submitted, George M. Wisner, Chief Engineer.
Hon. Henry L. Stimson, Secretary of War, Washington, D. C."

EXHIBIT "G" TO BILL OF COMPLAINT

In the Matter of the Application of THE TRUSTEES OF THE SANITARY DISTRICT OF CHICAGO for Permission to Divert from Lake Michigan 10,000 Cubic Feet of Water Per Second.

War Department

Washington, January 8, 1913.

The Sanitary District of Chicago applies to the War Department for permission to increase the amount of water it is authorized to withdraw from Lake Michigan from 4,167 cubic feet per second, the amount now authorized, to 10,000 cubic feet per second.

The Chicago Drainage Canal was opened in January, 1900. It reverses the flow of the Chicago River, which formerly emptied into Lake Michigan, and as a result a portion of the waters of that lake, instead of following their former course through Lakes Huron, Erie, and Ontario into the St. Lawrence, are now carried across the watershed into the Illinois River, and through that to the Mississippi and the Gulf of Mexico. The canal thus serves as a system of drainage for the City of Chicago, carrying the sewage of that city southward to the Mississippi, and thus protects the water supply of that city, which is taken from Lake Michigan.

[fol. 99] Permission to divert water from Lake Michigan was first granted by my predecessor, Secretary Alger, on May 8, 1899. He permitted a flowage of 5,000 cubic feet per second, but his permit contained the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it becomes apparent that the current created by such drainage works in the south and main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south branch.

Subsequently, during the administration of Secretary Root, the amount of the current permitted to be taken was modified or restricted until December 5, 1901, when it was fixed at the amount now permitted, and these permits contained the condition—

that the permission herein given shall be subject to such modifications as in the opinion of the Secretary of War the public interests may from time to time require.

On March 14, 1907, an application made for permission to divert an additional 4,000 cubic feet per second for the purpose of reversing the current of the Calumet River and flowing that river also through the canal to drain the southern portion of Chicago was denied by Secretary Taft in an opinion in which he referred once more to the desirability of submitting "this question of capital and national importance to the Congress of the United States."

It is clear that even under the conditions heretofore manifested on these applications, the proposition to divert the waters of Lake Michigan into another watershed has not been entertained without hesitation and careful restriction by my predecessors. The propriety of obtaining congressional sanction for the project has been pointed out from the beginning; and the form in which the permit has been granted, even for the moderate amount of diversion permitted, has been so phrased as to indicate that the permission was predicated upon the absence of any substantial injury to commerce.

The sanitary canal has never received the direct sanction of Congress. It was built solely under the authority of the State of Illinois, as given in its 1889 general act for creating sanitary districts. And although pursuant to the suggestion of my predecessors the question of the propriety of its diversion of water from Lake Michigan was presented urgently in the reports of the Chief of Engineers for the [fol. 100] years 1899 and 1900 as transmitted to Congress, no action upon the question has ever been taken by that body. In the argument before me it was urged that the present canal represented the growth and development of a national policy expressed in two acts of Congress, 1822 and 1827, which authorized the construction of a canal "to connect the Illinois River with Lake Michigan," thus connecting the two watersheds. (Acts of Mar. 30, 1822, and Mar. 2, 1827.) But these statutes authorized a canal for the purpose of navigation and not sanitation. (Missouri v. Illinois, 200 U. S. 526.) The Illinois and Michigan Canal, actually constructed under their authority, derived its water for navigation purposes from the Calumet, Des Plaines, and Chicago Rivers, and not from the Lakes. And although in the latter part of its existence it was used to a very slight extent to help purify the waters of the Chicago River and thus sanitate the City of Chicago, such a purpose could not have been dreamed of at the time its construction was authorized by Congress, 90 years ago. I can not see that its authorization and construction offer the slightest congressional sanction for the great canal now under discussion, which was not even contemplated until much more than half a century later. Even at the time when the present canal was constructed and opened it is very evident that its ultimate possible effect upon the navigation of the Great Lakes was not clearly realized by those interested in that navigation. The evidence before me indicates that the withdrawal of water from Lake Michigan at Chicago would require about five years to produce its full effect upon the levels of the Great Lakes (see report of International Waterways Commission on Chicago Drainage Canal, p. 7) and that this effect would be still further obscured by periodic oscillations in the lake levels. These facts may easily explain any inaction on the

part of the Nation and their representatives to this withdrawal of water and make it clear that any argument of implied acquiescence must be scrutinized with unusual care.

In this respect the situation is now very different. The present application was opposed by representatives of 23 cities and 6 States interested in harbors and commerce upon the Great Lakes, notably the Cities of Duluth, Milwaukee, Toledo, Cleveland and Buffalo. It was opposed by representatives of the navigation interests engaged on the Chicago River as well as on the Great Lakes, and by the official representatives of the Canadian Government as well as private Canadian interests engaged in the navigation of the Lakes and the [fol. 101] St. Lawrence River, including representatives of the Cities of Kingston and Montreal.

A very careful consideration of the voluminous evidence and statements submitted, as well as a consideration of the reports of other commissions and boards of engineers who have investigated the subject, leaves no doubt in my mind that the withdrawal of 10,000 cubic feet per second would substantially interfere with the navigable capacity of the Great Lakes and their connecting rivers. The Chief of Engineers, whose statutory authority in passing upon this application is concurrent with and independent of my own, and whose opinion upon such a question of scientific conclusion must be given especial weight, so states in his recommendation. His conclusions are corroborated by the authority of other boards of investigation, notably the report of the International Waterways Commission of January 4, 1907.

Careful observations and calculations conducted under the offices of the United States Lake Survey and reported through the Chief of Engineers, covering observations for the last 46 years, indicate that a withdrawal of 10,000 cubic feet per second would reduce levels at various places as follows:

	Inches
Lakes Huron and Michigan	6.9
Lake St. Clair	6.3
Lake Erie	5.4
Lake Ontario	4.5
St. Lawrence River at Rapide Plat	4.8 plus.

The foregoing effects would be produced at mean lake levels; the lowering effects would be much greater at low-water periods—the precise time when any additional shortage would be most keenly felt. This reduction would create substantial injury in all of the American harbors of the Great Lakes and in the St. Marys' St. Clair, and Detroit Rivers. It would produce equal injury in Canadian harbors on the Great Lakes, and a still greater injury on the lower St. Lawrence, the Canadian officials claiming a probable lowering effect of 12 inches at Montreal at low water.

The United States has improved about 106 harbors and rivers on the Great Lakes affected by this diversion and has spent on such improvements over ninety millions of dollars. The Canadian Government has improved over 50 harbors on Georgian Bay and Lakes

Huron, St. Clair, Erie and Ontario. By treaty, American vessels are accorded equal rights of navigation with Canadian vessels in all [fol. 102] these waters, including the St. Lawrence River. The reduction of the water in these harbors and channels would diminish to just that extent the amount of these improvements, and would nullify to just that extent the effects of the moneys which have been appropriated for that purpose by the respective Governments. Connecting various portions of these waterways are the two canals at the Sault Ste. Marie, the Welland Canal, and a number of canals on the St. Lawrence River. The available depth of water over one or all sills of each of these canals would be affected, and in some cases reconstruction might even be made necessary.

The enormous lake traffic which uses these harbors and these rivers is increasing with great rapidity, both in gross volume and in the size and average draft of the vessels employed therein. The Chief of Engineers reports that to lower the water surface 6 inches would reduce the permissible load of one of the large modern vessels by from 300 to 550 tons, with a consequent loss of from $3,600 to $7,500 in freights for such vessel per season. The International Waterways Commission reported that it would be a conservative estimate which would make the loss to the navigation interests resulting from a reduction of 6 inches in the depth of water as $1,500,000 per annum, or a sum which, capitalized at 4 per cent., would amount to a loss of $37,500,000. (see third progress report of International Waterways Commission of Dec. 1, 1907, p. 24). The lowest careful estimate of injury to American vessels alone is reported by the Chief of Engineers at $1,000,000 per year.

The argument was made before me that, owing to the well-known fact that the levels of the lake vary, owing to winds and change of barometric pressure, by amounts even greater than the reduction which would be caused by this canal, therefore the proposed reduction is of no consequence. This argument is well disposed of in the report of the International Waterways Commission of January 4, 1907, on page 8, as follows:

It is evident that the average level of the lake may be lowered considerably without the change becoming immediately apparent, and that fact has been used as an argument to prove that the lowering caused by the Chicago Drainage Canal is of no consequence to those interested in navigation. Since they cannot see it they will not know it and will not feel it. The argument is fallacious. It is true that they cannot see it immediately, but they will soon feel it and will know it through the most costly means of acquiring knowledge—the injury to their material interests. The oscillations will remain the same as before, but low water will fall lower and high water will rise less high. The average draft of vessels must be [fol. 103] diminished by the amount that the average level is lowered unless the depth be restored by remedial works.

In a word, every drop of water taken out of Chicago necessarily tends to nullify costly improvements made under direct authority of Congress throughout the Great Lakes, and a withdrawal of the amount now applied for would nullify such expenditures to the

amount of many millions of dollars, as well as inflict an even greater loss upon the navigation interests using such waters.

On the other hand, the demand for the diversion of this water at Chicago is based solely upon the needs of that city for sanitation. There is involved in this case no issue of conflicting claims of navigation. The Chief of Engineers reports that so far as the interests of navigation alone are concerned, even if we should eventually construct a deep waterway from the Great Lakes to the Mississippi over the route of the sanitary canal, the maximum amount of water to be diverted from Lake Michigan need actually be not over 1,000 feet per second, or less than a quarter of the amount already being used for sanitary purposes in the canal. This estimate is confirmed by the report of the special board of engineers on the deep waterway from Lockport, Ill., to the mouth of the Illinois River, dated January 23, 1911. It is also confirmed by the practical experience of the great Manchester Ship Canal in England. From the standpoint of navigation alone in such a waterway too great a diversion of water would be a distinct injury rather than a benefit. It would increase the velocity of the current and increase the danger of overflow and damage to adjacent lands.

We have, therefore, presented in this case claims of entirely different characters and jurisdictions—the claim of sanitation on the one side and of navigation on the other; the vital interest of a single community on the one side and the broad interest of the commerce of the nation on the other. The discretion given to the Secretary of War under sections 9 and 10 of the act of 1899 is very broad, but I have very grave doubts as to whether it was intended to authorize him to grant a permit which would inflict a substantial injury upon commerce in order to benefit sanitation. The entire purpose and scope of that legislation was to make him the guardian of commercial interests of the nation represented in their waterways. And while he sometimes under that statute must decide that the interests of one class of transportation are less important and must yield to the conflicting interests of another class, I have considerable doubt [fol. 104] whether it was intended to give him authority to sacrifice substantial interests of navigation to entirely different claims over which he normally has no jurisdiction whatever.

But however that may be, and without resting my decision upon the question of my legal authority, I am quite clear as a matter of discretion that under the facts presented by this case no further diversion of water should be permitted at Chicago without the direct sanction of the Congress of the United States. I do not for one moment minimize the importance of preserving the health of the great City of Chicago; but when a method of doing this is proposed which will materially injure a most important class of the commerce of the nation and which will also seriously affect the interests of a foreign power, it should not be done without the deliberate consideration and authority of the representatives of the entire nation. The growth of Chicago is phenomenal and its representatives are quite unwilling to put any final limit to the demand which may be made upon the waters of Lake Michigan for its sanitation under the

system now in use. I have before me the report of 1911 of the president of the sanitary district in which he says:

I am of the opinion that the presumption that our water supply is to be limited to 10,000 cubic feet per second, or 600,000 cubic feet per minute, is gratuitous and mischievous and should not be voiced by the officials of this district. I believe that we should have the volume requisite to our needs as they appear and are justified.

It is therefore quite conceivable that compliance with their sanitary needs according to this method of sanitation may eventually materially change this great natural watercourse now existing through the Lakes. The weighing of the sanitation and possibly the health of one locality over against the commerce of the rest of the Nation and the consideration of our relations and obligations to Canada in respect to a great international waterway are not matters of mere technical or scientific deduction. They are broad questions of national policy. They are quite different in character, for example, from the question of fixing the proper location of a pierhead line or the height or width of a drawbridge over a navigable stream—fair samples of the class of questions which come to the Secretary of War for decision under the above-mentioned act of 1899. While the researches and opinions of experts in the respective fields are necessary and useful as an assistance toward reaching a fair and proper policy, the final determination of that policy should belong not to an [fol. 105] administrative officer but rather to those bodies to whom we are accustomed to entrust the making of our laws and treaties.

In my view of the proper exercise of my discretion in this matter the foregoing considerations are sufficient for a decision of this case. Having reached the conclusion that the proposed diversion of the waters of Lake Michigan would substantially injure the interests of navigation on the Great Lakes which it is my legal duty to protect, it would clearly follow that the present application should be denied.

I have carefully examined, however, the evidence which both sides have introduced bearing upon the sanitary needs of the City of Chicago, and my conclusion is in no way shaken. I am not persuaded that the amount of water applied for is necessary to a proper sanitation of the City of Chicago. The evidence indicates that at bottom the issue comes down to the question of cost. Other adequate systems of sewage disposal are possible and are in use throughout the world. The problem that confronts Chicago is not different in kind but simply larger and more pressing than that which confronts all of the other cities on the Great Lakes, in which nearly 3,000,000 people of this country are living. The urban population of those cities, like that of Chicago, is rapidly increasing, and a method of disposition of their sewage which will not injure the potable character of the water of the Lakes must sooner or later be found for them all. The evidence before me satisfies me that it would be possible in one of several ways to at least so purify the sewage of Chicago as to require very much less water for its dilution than is now required by it in its unpurified condition. A recent report of the engineer of the sanitary commissior (Oct. 12, 1911) proposes

eventually to use some such method, but proposes to postpone its installation for a number of years to come, relying upon the present more wasteful method in the meanwhile. It is manifest that so long as the city is permitted to increase the amount of water which it may take from the Lakes, there will be a very strong temptation placed upon it to postpone a more scientific and possibly more expensive method of disposing of its sewage. This is particularly true in view of the fact that by so doing it may still further diminish its expenses by utilizing the water diverted from the Lakes for water power at Lockport. But it must be remembered that for every unit of horsepower realized by this water at Lockport four units of similar horsepower would be produced at Niagara, where the natural con- [fol. 106] ditions are so much more favorable. Without, therefore, going more into detail in a discussion of this question, I feel clear that no such case of necessity has been presented by the evidence before me as would justify the proposed injury to the many varied interests in the great waterways of our lakes and their appurtenant rivers.

It remains only to consider certain special arguments that have been pressed upon me. It has been urged that the levels of the lakes, even if lowered, could be restored by compensating works. To a certain extent that is true. But the very nature of this consideration offers another illustration of the importance of having the whole question passed upon by Congress. Such compensating works can only be constructed by the authority of Congress and at very considerable cost. It is not a matter which is in the hands of the Secretary of War. Permission to divert water which will at one and the same time nullify the effect of past appropriations and make necessary similar expenditures in the future, should be granted only with the express consent of the body in whose hands the making of such appropriations and the authorization of such works rest.

Furthermore, in most cases such compensating works could only be constructed with the joint consent of our neighbor Canada. The United States Government alone would be unable, even if it were willing to spend its own funds, to compensate for the damage done through the lowering of these levels unless Canada were willing to join in constructing the portion of such works which would necessarily stand upon Canadian soil.

The question therefore becomes not merely national but international, and this leads me to the consideration of the arguments which were urged by both sides in reference to the treaty with Great Britain in respect to Canada of January 11, 1909. A careful consideration of that treaty fails to indicate to me that it is in any way controlling upon the questions now before me. It gives to the citizens of both countries certain mutual rights of navigation in the waters of the Great Lakes and their connecting rive-s; but beyond that the question of the right to this diversion at Chicago seems to me to have carefully excluded. The applicants for the permit have urged upon me that article 8 of the treaty gives a preference to the uses of water of the lakes for domestic and sanitary purposes over the uses of such water for navigation. Article 8, however, applies only to future

[fol. 107] cases brought before the International Joint Commission; and furthermore I am clearly of the opinion that the domestic and sanitary purposes referred to in that article were intended to be the "ordinary" uses of such waters for domestic and sanitary purposes referred to in article 3. It would be quite contrary to our own national policy to give such a preference to an extraordinary sanitary use of such a character as to create a substantial injury to navigation. The matter has been before our own Supreme Court in the case of the United States v. the Rio Grande Dam & Irrigation Co. (174 U. S., 690). In that case the Supreme Court held that a company which proposed to take the water of the Rio Grande river for the purpose, among others, "of supplying water to cities and towns for domestic and municipal purposes" could be prevented from so doing when the result would be a substantial injury to the navigability of the Rio Grande river farther down. In its opinion the court said:

The question always is one of fact, whether such appropriation substantially interferes with the navigable capacity within the limits where navigation is a recognized fact. In the course of the argument, this suggestion was made, and it seems to us not unworthy of note, as illustrating this thought. The Hudson river runs within the limits of the State of New York. It is a navigable stream and a part of the navigable waters of the United States, so far at least as from Albany southward. One of the streams which flows into it and contributes to the volume of its waters is the Croton river, a non-navigable stream. Its waters are taken by the State of New York for domestic uses in the City of New York. Unquestionably the State of New York has a right to appropriate its waters, and the United States may not question such appropriation, unless thereby the navigability of the Hudson be disturbed. On the other hand, if the State of New York should, even at a place above the limits of navigability, by appropriation for any domestic purposes, diminish the volume of waters, which, flowing into the Hudson, make it a navigable stream, to such an extent as to destroy its navigability, undoubtedly the jurisdiction of the National Government would arise and its power to restrain such appropriation be unquestioned; and within the purview of this section (act of Sept. 19, 1890, ch. 907) it would become the right of the Attorney General to institute proceedings to restrain such appropriation.

The treaty, however, contains provisions in its article 10 by which "any questions or matters of difference arising between the high contracting parties involving the rights, obligations, or interests of the United States or of the Dominion of Canada, either in relation to each other or to their respective inhabitants, may be referred for decision" to an international joint commission established by the said treaty. The hearing before me brought forth the fact that the Government of Canada regards the proposal contained in this application as one which affects the material interests of that county. The establishment by formal treaty between the two countries of a tribunal [fol. 108 & 109] with jurisdiction to decide just such questions seems to me to afford an additional reason against the assumption of juris-

diction to decide the question by an administrative officer of one of those countries.

In short, after a careful consideration of all the facts presented, I have reached the following conclusions:

First. That the diversion of 10,000 cubic feet per second from Lake Michigan, as applied for in this petition, would substantially interfere with the navigable capacity of the navigable waters in the Great Lakes and their connecting rivers.

Second. That that being so, it would not be appropriate for me, without express congressional sanction, to permit such a diversion, however clearly demanded by the local interests of the sanitation of Chicago.

Third. That on the facts here presented no such case of local permanent necessity is made evident.

Fourth. That the provisions of the Candian treaty for a settlement by joint commission of "questions or matters of difference" between the United States and Canada offer a further reason why no administrative officer should authorize a further diversion of water, manifestly so injurious to Canada, against Canadian protest.

The prayer of the petition is therefore denied.

Henry L. Stimson, Secretary of War.

[File endorsement omitted.]

[fol. 110] District Court of the United States, Northern District of Illinois

United States of America, Complainant,

vs.

The Sanitary District of Chicago, Defendant.

The Answer of the Sanitary District of Chicago, Defendant, to the Bill of Complaint of the United States of America, Complainant—Filed January 16, 1914

[fol. 111] This defendant, The Sanitary District of Chicago, by Edmund D. Adcock and Alfred S. Austrain, its solicitors, now, and at all times hereinafter saving and reserving unto itself all benefit and advantage of exception which can or may be had or taken to the many errors, uncertainties and other imperfections in said bill contained for answer thereunto, or to so much or such parts thereof as this defendant is advised, it is or are material or necessary for it to make answer unto answering says:

1. This defendant admits that it is a municipal corporation, organized and existing under and by virtue of the laws of the State

of Illinois, as charged in the first paragraph of the Bill of Complaint, filed herein, and this defendant hereto attaches a copy of the Act of the General Assembly of the State of Illinois, entitled "An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illnois Rivers," approved May 29, 1889, in force July 1, 1889, [fol. 112] and all acts amendatory and supplementary thereto, marked "Exhibit A" and made a part hereof, to which reference is hereby made.

2. This defendant admits that the Chicago River is situated in the County of Cook and State of Illinois and consists of a main river, originaly flowing in a generally easterly direction, emptying into Lake Michigan; that said main river is formed by two branches, known as the North Branch and the South Branch respectively; that said South Branch is divided into two forks, known as the West Fork and the South Fork, and this defendant attaches hereto a map or plat, marked "Exhibit B" and made a part hereof, which said plat more particularly describes said river, its branches and forks and shows the exact location and direction of the same, to which said "Exhibit B" reference is hereby made.

3. This defendant admits that the said Chicago River including both the North Branch and South Branch as well as the West Fork and South Fork of the South Branch are navigable waters of the United States.

4. This defendant admits that the United States of America has appropriated and expended large sums of money to-wit: the sum of $4,216,066.33 in improving the navigable capacity of said river and the harbor at the mouth of the same, as is charged in paragraph 4 of the Bill of Complaint, filed herein, and this defendant shows that of the said sum, the said complainant expended, to wit: the sum of $2,389,527.10, in and about the improvement of the harbor at the mouth of the said Chicago River; that no part of said latter sum was expended in or about the improvement of said Chicago River; that down to the year 1896 the said complainant had expended no money whatever in the improvement of the said Chicago River; that the balance of said sum of $4,216,066.36, to wit: the sum of $1,626,539.29 was expended by the complainant in and about the improvement of the Chicago River between the year 1896 and the [fol. 113] 30th day of June, 1913; that the City of Chicago, prior to the expenditure by the United States of any money on the Chicago River, began the improvement of said river and expended large sums of money in said improvement; that the City of Chicago entered upon the improvement of the said Chicago River in the year 1861 and has expended during the period beginning in the said year, 1861, and ending the first day of January, 1913, the sum of, to wit: $6,272,574.52; that this defendant has itself expended in addition to the money expended by the City of Chicago, the sum of, to wit: $10,640,739.52, in and about the improvement of the said Chicago River, the South Branch and West Fork thereof; that the said moneys so expended by this defendant was expended for the

purpose of enabling this defendant to cause to flow the several amounts of water through the said river as provided under the Act of the General Assembly of Illinois of 1889 and all of said expenditures improved the capacity and navigability of said Chicago River and its several branches.

5. This defendant admits that the provisions of Section 10 of an Act of Congress, approved March 3, 1889, entitled "An Act making appropriations for the construction, repair and preservation of certain public works on rivers, harbors and for other purposes" are substantially as set forth in paragraph 5 of the Bill of Complaint filed herein; that the said Act of Congress has remained in full force and effect ever since its passage and still remains in full force and effect.

6. This defendant admits that the Secretary of War on, to wit, the 8th day of May, 1899, issued a permit to this defendant granting it permission to open the channel constructed and cause the waters of the Chicago River to flow into the same, that the said permit is substantially in words and figures as set forth in the said Bill of Complaint as "Exhibit A" thereto. This defendant denies that applica-[fol. 114] tion was made by this defendant for permission to abstract and divert a certain quantity of water from Lake Michigan through the said main channel of this defendant, but this defendant shows that application was made to the Secretary of War for permission to open the channel constructed and cause the waters of the Chicago River to flow into the same pursuant to and under the said Act of May 29th, 1889, hereinbefore set forth, that in the said permit the said Secretary of War stated that he reserved the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch.

7. This defendants admits that on, to wit: April 9, 1901, the Secretary of War ordered and directed this defendant to reduce the flow through the Chicago River to 200,000 cubic feet of water per minute as charged in paragraph 7 of said bill; that the provisions of said order are substantially as set forth in the said Bill of Complaint as "Exhibit B" thereto.

8. This defendant admits that on or about July 23, 1901, the Secretary of War modified the order theretofore issued on April 9, 1901, as aforesaid by issuing a permit to defendant to flow 300,000 cubic feet of water per minute through the Chicago River between the hours of 4:00 P. M. and 12:00 P. M. midnight; that the provisions of the said permit are set forth in the Bill of Complaint as "Exhibit C."

9. This defendant admits that on or about the 5th day of December, 1901, the Secretary of War issued a permit to defendant to cause the flow 250,000 cubic feet of water per minute throughout the twenty-four hours of the day; that the provisions of said permit are substantially as is set forth in said Bill of Complaint as "Exhibit D" thereto.

10. This defendant admits that on or about the 17th day of January, 1903, the Secretary of War issued a permit to the defendant to increase the flow of water through the Chicago River from 250,-[fol. 115] 000 to 300,000 cubic feet of water per minute until the 31st day of March, 1903, after which time the flow to be reduced to 250,000 cubic feet of water per minute; that the provisions of the said permit are substantially as is set forth in the said Bill of Complaint as "Exhibit E" thereto.

11. This defendant admits that on or about the 28th day of November, 1906, this defendant made application to the Secretary of War for permission to construct a canal connecting the Calumet River with the main channel of the defendant at what is known as Sag Station, as charged in paragraph 11 of said Bill of Complaint; that thereafter on or about the 14th day of March, 1907, the said Secretary of War denied the said application and refused to grant the permit applied for thereunder; that a copy of the said statement of the Secretary of War denying said permit is by express reference thereto, made part hereof, and marked "Exhibit C," and attached hereto.

12. This defendant admits that on or about the 11th day of September, 1907, this defendant applied for and obtained from the Secretary of War a permit to construct a canal connecting Lake Michigan at Wilmette, Illinois, with the North Branch of the Chicago River; that a copy of the said permit is by express reference thereto, made a part hereof and is attached hereto and marked "Exhibit D."

13. This defendant admits that on or about the 30th day of June, 1910, this defendant applied for and obtained permission from the Secretary of War authorizing it to construct a canal connecting the Calumet River with the main channel of this defendant at Sag, Illinois, and to reverse the flow of the Calumet River, that the said canal is known and described as the Sag Channel, that a copy of the said permit issued on said, to-wit: June 30, 1910, is by express reference thereto, made a part hereof and is attached hereto and marked "Exhibit E."

[fol. 116] 14. This defendant admits that on or about the 5th day of February, 1912, this defendant applied to the Secretary of War for a permit to withdraw and divert from Lake Michigan through the Chicago and Calumet Rivers at least the amount of 10,000 cubic feet of water per second or 600,000 cubic feet of water per minute as charged in paragraph 14 of said Bill of Complaint; copy of which said application is attached to said Bill of Complaint and marked "Exhibit F."

15. This defendant admits that on, to-wit: the 8th day of January, 1913, the Secretary of War refused said application of February 5, 1912; that the statement of the Secretary of War in refusing the said application is set forth as "Exhibit G" to said Bill of Complaint.

16. This defendant denies that it has for a long period of time diverted and abstracted from Lake Michigan and caused to flow through the Chicago River, or that it is at the present time diverting and abstracting from Lake Michigan and causing to flow through the Chicago River from 400,000 to 600,000 cubic feet of water per minute as charged in paragraph 16 of said Bill of Complaint.

17. This defendant denies that the diversion and abstraction of the waters of Lake Michigan into the Chicago River substantially in excess of the amount of 250,000 cubic feet of water per minute has lowered or will lower the levels of Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie, Lake Ontario, Sault Ste Marie, St. Mary's River, St. Clair River, Detroit River, Niagara River and St. Lawrence River, or any of them, or of any of the harbors, channels, canals or rivers connected therewith or will injure or diminish or create an obstruction to the navigable capacity of said waters or any of them as charged in paragraph 18 of said Bill of Complaint.

18. This defendant neither affirms nor denies that the said waters mentioned in paragraph 18 of the said Bill of Complaint have been deepened and improved under great expense to the complainant, [fol. 117] under the authority of Congress but prays for strict proof thereof; and this defendant denies that the diversion and abstraction of waters from Lake Michigan substantially in excess of the permits hereinabove set forth have, or will have a tendency to undo or annul the orders or acts of Congress as charged in paragraph 19 of said Bill of Complaint.

19. This defendant denies that the said diversion and abstraction of the waters of Lake Michigan through the Chicago River in excess of or substantially in excess of the amount provided by the permit of the Secretary of War as aforesaid will modify the condition and capacity of the channel of the said Chicago River as charged in paragraph 20 of said Bill of Complaint.

20. This defendant denies that the said diversion and abstraction of waters of Lake Michigan through the Chicago River in excess of or substantially in excess of the permits of the Secretary of War as aforesaid, will alter or modify the condition and capacity of Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie, Lake Ontario, Sault Ste Marie, St. Mary's River, St. Clair River, Detroit River, Niagara River and St. Lawrence River, or any of them, and the ports, roadsteads, havens, harbors, canals and harbors of refuge connected with the above named waters or any of them. This defendant denies that it cannot lawfully continue to divert and abstract without the permission of the Secretary of War, waters from Lake Michigan as it now does or that it cannot lawfully divert and abstract without the permission of the Secretary of War waters from Lake Michigan under the said Act of the General Assembly of the State of Illinois approved May 29th, 1889, and by and through the channels and works it has already constructed. And this defendant denies that the complainant will be in any manner injured by the diversion of

waters pursuant to said Act of the General Assembly of the State of [fol. 118] Illinois; and this defendant denies that the Interstate Navigation and Commerce of the United States will in any manner or to any extent be injured or destroyed by the proposed abstraction or diversion of water from Lake Michigan pursuant to and under said Act of the General Assembly of the State of Illinois of May 29, 1889, and as contemplated by the channels and works of this defendant hereinbefore and hereafter described.

21. This defendant states that the Sanitary District of Chicago is a municipal subdivision of the State of Illinois, consisting of an area of 386.2 square miles, situated on the shore of Lake Michigan at the southwestern end of said lake, with a shore line on said Lake Michigan of 33 miles and extending westward from said shore line, a distance of from 6 to 14 miles; that the land lying within the said territory is naturally drained into Lake Michigan for the most part through the Chicago and Calumet Rivers and their branches; that rising in the State of Wisconsin about 12 miles back from the shore of Lake Michigan, is the Desplaines River which flows in a southerly direction at a distance of about 10 miles from said lake and parallel to said lake until it, the said Desplaines River, reaches a point 15 miles southwest of the mouth of the Chicago River, when it turns to the southwest and at a distance of 45 miles beyond empties into the Illinois River; that at a distance of about 6 miles back from Lake Michigan and between said Lake Michigan and the Desplaines River is an elevation of land of approximately 11 feet above the low water level of Lake Michigan; that said elevation of land has been known as the Continental Divide, or the height of land on one side of which water flows into the Great Lakes thence into the Gulf of St. Lawrence, and on the other side of which water flows into the Desplaines River, thence into the Illinois and Mississippi Rivers, thence to the Gulf of Mexico; that the lowest point in said Continental Divide or elevation [fol. 119] of land was at a point about 8 miles by the water trail southwest of the mouth of the Chicago River; that at said point there was situated approximately on the summit of said divide a lake known as Portage *Land* and later as Mud Lake; that in times of high water the Desplaines River rose to the elevation of said lake and discharged itself over the divide and through the Chicago River into Lake Michigan; that the land lying to the East of said divide is low, flat, level and swampy land absolutely devoid of hills or elevations of land so that in times of high water large portions of said territory were overflowed; that the City of Chicago was established at the mouth of the Chicago River located approximately in the center of the territorial limits of this defendant; that the City of Chicago as it has expanded has stretched out over the branches of the Chicago River and over the territory of this defendant and from the time when the site where the City of Chicago is now located, was settled it has been menaced by floods and has had to contend with the natural disadvantages which it suffered by reason of the fact that the city was situated upon a flat, low, sandy soil and at the outlet or discharging point of a large drainage area; that from the various
